LIFE SUPPORT POLICY

Decawave products are not authorized for use in safety-critical applications (such as life support) where a failure of the Decawave product would reasonably be expected to cause severe personal injury or death. Decawave customers using or selling Decawave products in such a manner do so entirely at their own risk and agree to fully indemnify Decawave and its representatives against any damages arising out of the use of Decawave products in such safety-critical applications.

Caution! ESD sensitive device.

Precaution should be used when handling the device in order to prevent permanent damage

DISCLAIMER

This Disclaimer applies to the DW3000 API source code (collectively “Decawave Software”) provided by Decawave Ltd. (“Decawave”).

Downloading, accepting delivery of or using the Decawave Software indicates your agreement to the terms of this Disclaimer. If you do not agree with the terms of this Disclaimer do not download, accept delivery of or use the Decawave Software.

Decawave Software is solely intended to assist you in developing systems that incorporate Decawave semiconductor products. You understand and agree that you remain responsible for using your independent analysis, evaluation and judgment in designing your systems and products. THE DECISION TO USE DECAWAVE SOFTWARE IN WHOLE OR IN PART IN YOUR SYSTEMS AND PRODUCTS RESTS ENTIRELY WITH YOU.

DECAWAVE SOFTWARE IS PROVIDED "AS IS". DECAWAVE MAKES NO WARRANTIES OR REPRESENTATIONS WITH REGARD TO THE DECAWAVE SOFTWARE OR USE OF THE DECAWAVE SOFTWARE, EXPRESS, IMPLIED OR STATUTORY, INCLUDING ACCURACY OR COMPLETENESS. DECAWAVE DISCLAIMS ANY WARRANTY OF TITLE AND ANY IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT OF ANY THIRD PARTY INTELLECTUAL PROPERTY RIGHTS WITH REGARD TO DECAWAVE SOFTWARE OR THE USE THEREOF.

DECAWAVE SHALL NOT BE LIABLE FOR AND SHALL NOT DEFEND OR INDEMNIFY YOU AGAINST ANY THIRD PARTY INFRINGEMENT CLAIM THAT RELATES TO OR IS BASED ON THE DECAWAVE SOFTWARE OR THE USE OF THE DECAWAVE SOFTWARE WITH DECAWAVE SEMICONDUCTOR TECHNOLOGY. IN NO EVENT SHALL DECAWAVE BE LIABLE FOR ANY ACTUAL, SPECIAL, INCIDENTAL, CONSEQUENTIAL OR INDIRECT DAMAGES, HOWEVER CAUSED, INCLUDING WITHOUT LIMITATION TO THE GENERALITY OF THE FOREGOING, LOSS OF ANTICIPATED PROFITS, GOODWILL, REPUTATION, BUSINESS RECEIPTS OR CONTRACTS, COSTS OF PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION), LOSSES OR EXPENSES RESULTING FROM THIRD PARTY CLAIMS. THESE LIMITATIONS WILL APPLY REGARDLESS OF THE FORM OF ACTION, WHETHER UNDER STATUTE, IN CONTRACT OR TORT INCLUDING NEGLIGENCE OR ANY OTHER FORM OF ACTION AND WHETHER OR NOT DECAWAVE HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH DAMAGES, ARISING IN ANY WAY OUT OF DECAWAVE SOFTWARE OR THE USE OF DECAWAVE SOFTWARE.

You are authorized to use Decawave Software in your end products and to modify the Decawave Software in the development of your end products. HOWEVER, NO OTHER LICENSE, EXPRESS OR IMPLIED, BY ESTOPPEL OR OTHERWISE TO ANY OTHER DECAWAVE INTELLECTUAL PROPERTY RIGHT, AND NO LICENSE TO ANY THIRD PARTY TECHNOLOGY OR INTELLECTUAL PROPERTY RIGHT, IS GRANTED HEREIN, including but not limited to any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which Decawave semiconductor products or Decawave Software are used.

You acknowledge and agree that you are solely responsible for compliance with all legal, regulatory and safety-related requirements concerning your products, and any use of Decawave Software in

your applications, notwithstanding any applications-related information or support that may be provided by Decawave.

Decawave reserves the right to make corrections, enhancements, improvements and other changes to its software at any time.

1 INTRODUCTION AND OVERVIEW

The DW3000 IC is a radio transceiver IC implementing the UWB HRP physical layer defined in IEEE 802.15.4 standard [3]. For more details of this device the reader is referred to:

- The Data Sheet [1]
- The User Manual [2]

This document, “*DW3000 Device Driver - Application Programming Interface (API) Guide*” is a guide to the device driver software developed by Decawave to drive Decawave’s DW3000 UWB radio transceiver IC.

The device driver is essentially a set of low-level functions providing a means to exercise the main features of the transceiver without having to deal with the details of accessing the device directly through its SPI interface register set.

The device driver is provided as source code to allow it to be ported to any target microprocessor system with an SPI interface¹. The source code employs the C programming language.

The device driver is controlled through its Application Programming Interface (API) which is comprised of a set of functions. This document is predominately a guide to the device driver API describing each of the API functions in detail in terms of its parameters, functionality and utility.

This document relates to: **"DW3000 Device Driver Version 04.00.xx"**

The device driver version information may be found in source code file “[deca_version.h](#)”.

¹ Since the DW3000 is controlled through its SPI interface, an SPI interface is a mandatory requirement for the system.

2 GENERAL FRAMEWORK

Figure 1 shows the general framework of the software system encompassing the DW3000 device driver. The device driver controls the IC through its SPI interface. The device driver abstracts the target SPI device by calling it through generic functions `writetospi()` and `readfromspi()`. In porting the IC device driver to different target hardware, the body of these SPI functions are written/re-written/provided to drive the target microcontroller device's physical SPI hardware. The initialisation of the physical SPI interface mode and data rate is considered to be part of the target system outside the IC device driver.

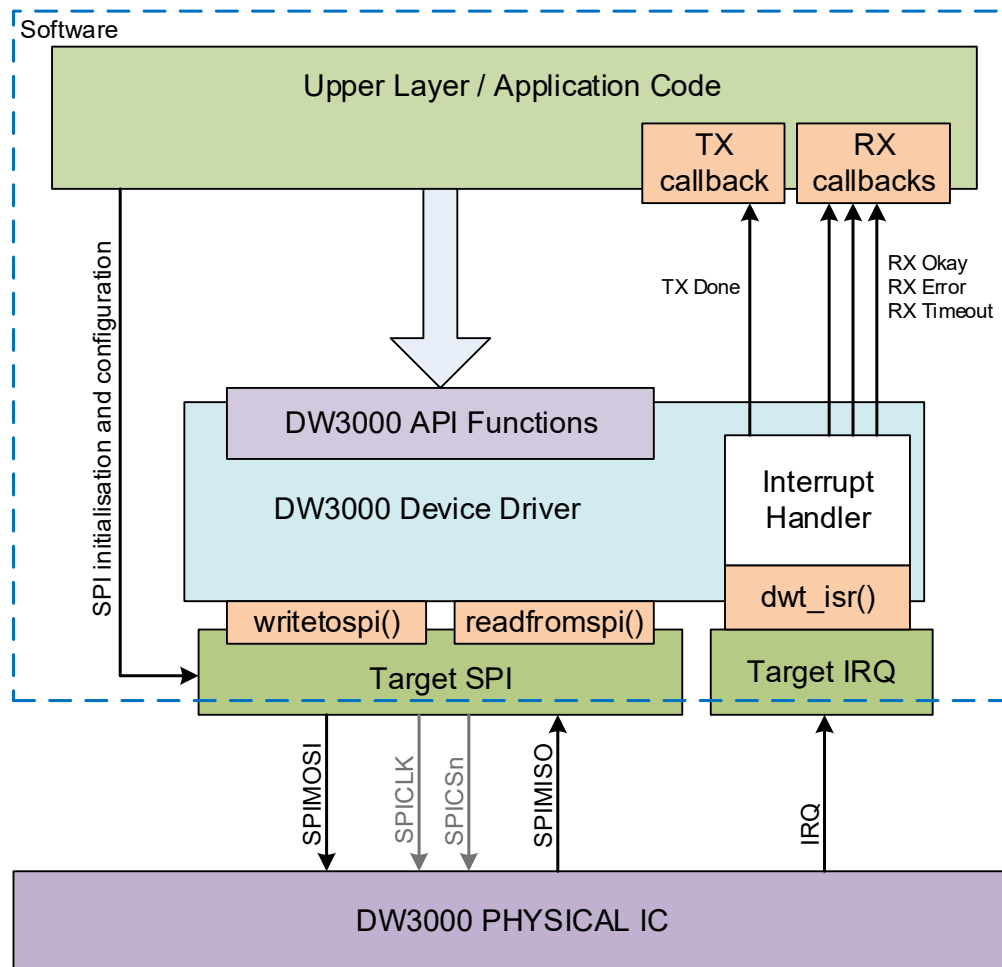

Figure 1: General software framework of the device driver

The control of the IC through the device driver software is achieved via a set of API functions, documented in section 5 – [API function descriptions](#) below, and called from the upper layer application code.

The IRQ interrupt line output from the IC (assuming interrupts are being employed) is connected to the target microcontroller system's interrupt handling logic. Again, this is considered to be outside the device driver. It is assumed that the target systems interrupt handling logic and its associated

target specific interrupt handling software will correctly identify the assertion of the IC's IRQ and will as a result call the device driver's interrupt handling function [dwt_isr\(\)](#) to process the interrupt.

The device driver's [dwt_isr\(\)](#) function processes the IC interrupts and calls TX, RX, RX error, RX timeout, SPI error or SPI ready call-back functions in the upper layer application code. This is done via function pointers [*cbTxDone\(\)](#), [*cbRxOk\(\)](#), [*cbRxTo](#), [*cbRxErr\(\)](#), [*cbSPIErr\(\)](#) and [*cbSPIRdy\(\)](#) which are configured to call the upper layer application code's own call-back functions via the [dwt_setcallbacks\(\)](#) API function.

Using interrupts is recommended, but it is possible to drive the IC without employing interrupts. In this case the background loop can periodically call the device driver's [dwt_isr\(\)](#) function, which will poll the IC status register and process any events that are active.

The following is IMPORTANT:

Note *background* application activity invoking API functions employing the SPI interface can conflict with *foreground* interrupt activity also needing to employ the SPI interface.

The device driver's interrupt handler accesses the IC through the [writetospi\(\)](#) and [readfromspi\(\)](#) functions, and, it is generally expected that the call-back functions will also access the IC through the device driver's API functions which ultimately also call the [writetospi\(\)](#) and [readfromspi\(\)](#) functions.

This means that the [writetospi\(\)](#) and [readfromspi\(\)](#) functions need to incorporate protection against *foreground* activity occurring when they are being used in the *background*. This is achieved by incorporating calls to [decamutexon\(\)](#) and [decamutexoff\(\)](#) within the [writetospi\(\)](#) and [readfromspi\(\)](#) functions to disable interrupts from the IC from being recognised while the *background* SPI access is in progress.

Examples of be [decamutexon\(\)](#) and [decamutexoff\(\)](#) within the [writetospi\(\)](#) and [readfromspi\(\)](#) functions found in source code file "[deca_irq.c](#)" and the definitions of the [writetospi\(\)](#) and [readfromspi\(\)](#) functions in "[deca_spi.c](#)" source file.

Other than the provisions for interrupt handling, the device driver and its API functions are not written to be re-entrant or for simultaneous use by multiple threads. The design in general assumes a single caller that allows each function to complete before it is called again.

3 TYPICAL SYSTEM START-UP

Figure 2 shows the typical flow of initialisation of the DW3000 in a microprocessor system.

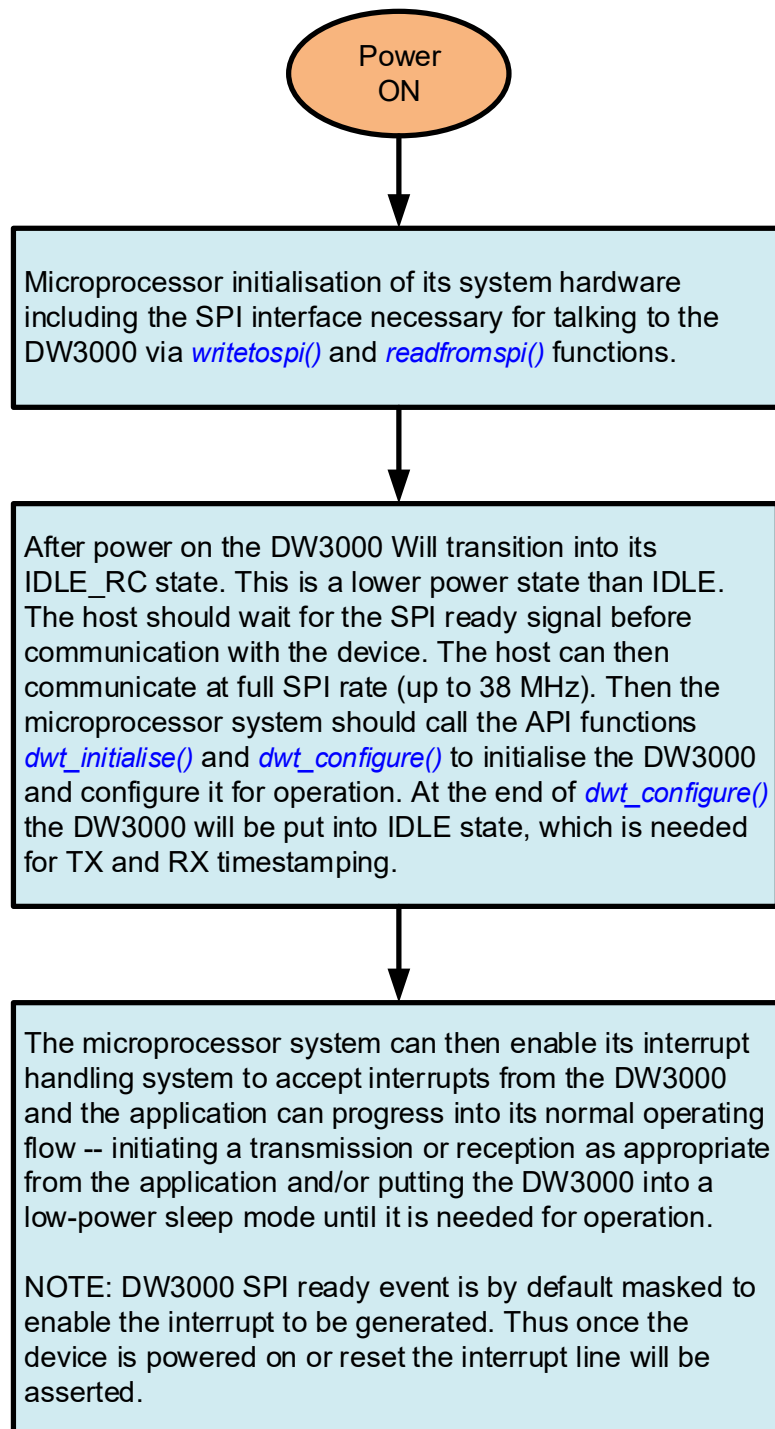

Figure 2: Typical flow of initialisation

4 INTERRUPT HANDLING

Figure 3 shows how the DW3000 interrupts should be processed by the microcontroller system. Once the interrupt is active, the microcontroller's target specific interrupt handler for that interrupt line should get called. This in turn calls the device driver's interrupt handler service routine, the `dwt_isr()` API function, which processes the event that triggered the interrupt.

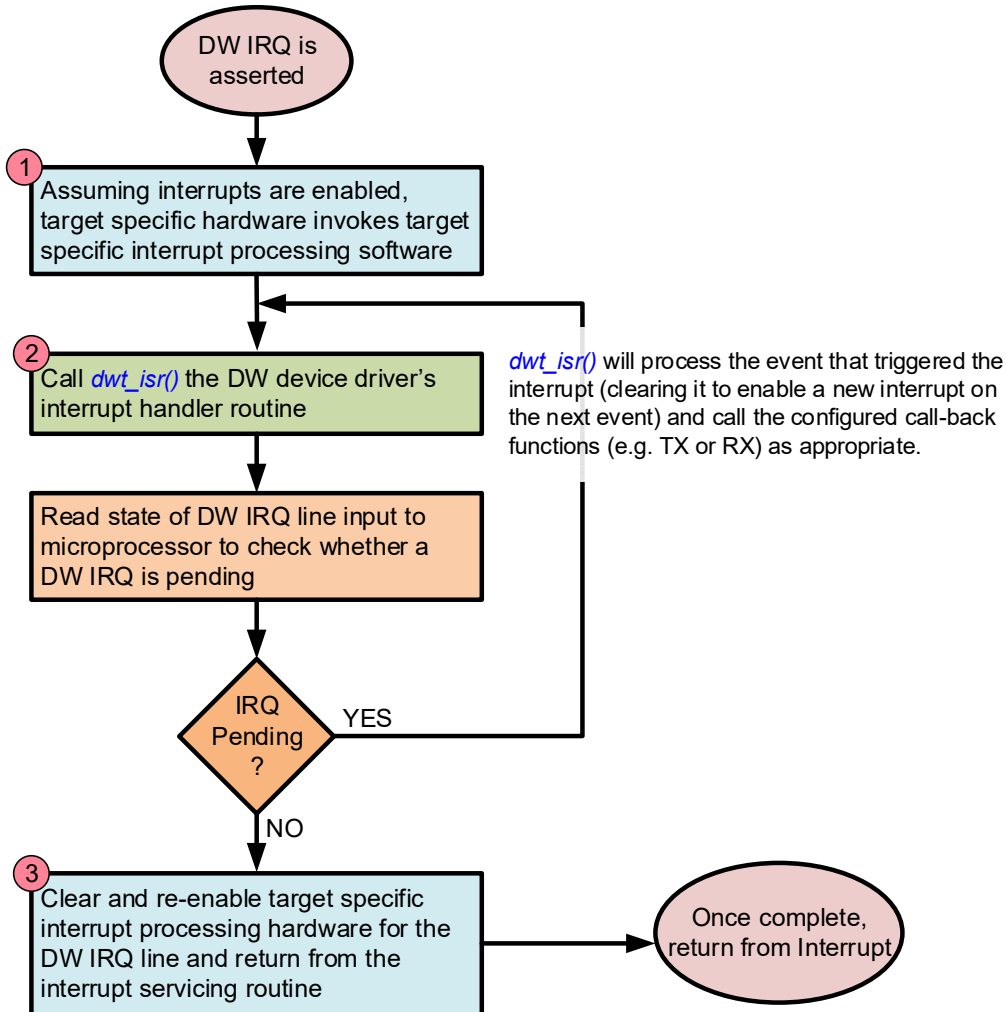

Figure 3: Interrupt handling

The flow shown above, with the rechecking of continued IRQ line activation and calling the `dwt_isr()` API function again, is only required for edge sensitive interrupts. This is done in case another interrupt becomes pending during the processing of the first interrupt, in this case if all interrupt sources are not cleared the IRQ line will not be de-asserted and edge sensitive interrupt processing hardware will not see another edge. For proper level sensitive interrupts only steps numbered 1, 2, and 3 are required – any still pending interrupt should cause the interrupt handler to be re-invoked as soon as it finishes processing the first interrupt.

More information about individual interrupt events and associated processing is shown in Figure 6.

5 API FUNCTION DESCRIPTIONS

This section describes device driver's API function calls. The API functions are provided to aid developers in driving the DW3000 (Decawave's IEEE 802.15.4 [3] UWB transceiver IC).

These functions are implemented in the device driver source code file "[deca_device.c](#)", written in the 'C' programming language.

The device driver code interacts with the IC using simple SPI read and write functions. These are abstracted from the physical hardware, and are easily ported to any specific SPI implementation of the target system. There are two SPI functions: [writetospi\(\)](#) and [readfromspi\(\)](#) these prototypes are defined in the source code file "[deca_spi.c](#)".

The functions of the device driver are covered below in individual sub-sections.

5.1 Initialise APIs

5.1.1 dwt_apiversion

```
int32_t dwt_apiversion(void);
```

This function returns the version of the API as defined by DW3000_DRIVER_VERSION.

Parameters:

none

Return Parameters:

type	Description
int32_t	Driver version e.g. 0x030000

Notes:

5.1.2 dwt_readdevid

```
uint32_t dwt_readdevid(void);
```

This function returns the device identifier (DEV_ID) register value (32-bit value). It reads the DEV_ID register (0x00) and returns the result to the caller. This may be used for instance by the application to verify the DW IC is connected properly over the SPI bus and is running.

Parameters:

none

Return Parameters:

type	Description
uint32_t	32-bit device ID value, e.g. for DW3000 the device ID is 0xDECA03xx.

Notes:

This function can be called any time to read the device ID value. A return value of 0xFFFFFFFF or 0x0 indicates an error unless the device is in DEEP_SLEEP or SLEEP mode.

Example code:

```
uint32_t devID = dwt_readdevvid();
```

5.1.3 dwt_check_dev_id

```
int dwt_check_dev_id(void);
```

This function checks if the device ID that is being read back from the DEV_ID register is a correct value. If the device ID is incorrect, it can mean that either something is wrong with the SPI reads to the DW3000, or the driver is reading a device ID from an incompatible version of hardware. The latter can occur if a newer version of the software is used to try read from an older version of hardware. It is useful to run this function upon initialisation.

Parameters:

none

Return Parameters:

type	Description
int	DWT_SUCCESS is returned if the device ID read back from the device is correct. DWT_ERROR is returned if the device ID does not conform with this version of software.

Notes:

Calling this function upon initialisation can be beneficial in cases where there is potential for versions of software and hardware to be out of sync.

Example code:

```
/* Reads and validate device ID returns DWT_ERROR if it does not match
expected else DWT_SUCCESS */
int err;

if ((err=dwt_check_dev_id())==DWT_SUCCESS)
{
    printf("DEV ID OK\n");
}
else
{
    printf("DEV ID FAILED\n");
}
```

5.1.4 dwt_getpartid

```
uint32_t dwt_getpartid(void);
```

This function returns the part identifier as programmed in the factory during device test and qualification. ([dwt_initialise\(\)](#) must be called prior to this)

Parameters:

none

Return Parameters:

type	description
uint32_t	32-bit part ID value.

Notes:

This function can be called any time to read the locally stored value which will be valid after device initialisation is done by a call to the [dwt_initialise\(\)](#) function.

Example code:

```
uint32_t partID = dwt_getpartid();
```

5.1.5 dwt_getlotid**uint32_t dwt_getlotid(void);**

This function returns the lot identifier as programmed in the factory during device test and qualification. ([dwt_initialise\(\)](#) must be called prior to this)

Parameters:

none

Return Parameters:

type	description
uint32_t	32-bit lot ID value.

Notes:

This function can be called any time to read the locally stored value which will be valid after device initialisation is done by a call to the [dwt_initialise\(\)](#) function.

Example code:

```
uint32_t lotID = dwt_getlotid();
```

5.1.6 dwt_geticrefvolt**uint8_t dwt_geticrefvolt(void);**

During the IC manufacturing test, a 1.8 volt reference level is applied to the power the device and the battery voltage reported by the battery voltage monitor SAR A/D convertor is sampled and programmed into OTP address 0x8 (VBAT_ADDRESS). This reference value may be used to calibrate/interpret battery voltage monitor values during IC use. The [dwt_geticrefvolt\(\)](#) function returns this factory reference voltage value.

Parameters:

none

Return Parameters:

type	description
uint8_t	8-bit V measured value at 1.8 V.

Notes:

This function can be called any time to read the locally stored value which will be valid after device initialisation is done by a call to the [dwt_initialise\(\)](#) API function.

5.1.7 dwt_geticreftemp**uint8_t dwt_geticreftemp(void);**

During the IC manufacturing test, in a controlled environment with approximately 23 °C ambient temperature the temperature monitor SAR A/D convertor is sampled and programmed into OTP address 0x9 (VTEMP_ADDRESS). This reference value may be used to calibrate/interpret temperature monitor values during IC use. The [dwt_geticreftemp\(\)](#) API function returns this factory reference temperature value.

Parameters:

none

Return Parameters:

type	description
uint8_t	8-bit Temperature measured value at 23 °C.

Notes:

This function can be called any time to read the locally stored value which will be valid after device initialisation is done by a call to the [dwt_initialise\(\)](#) API function.

5.1.8 dwt_getxtaltrim**uint8_t dwt_getxtaltrim(void);**

This function returns the current value of XTAL trim. If called after [dwt_initialise\(\)](#) API on power up, it will either contain crystal trim value loaded from OTP memory or a default value.

Parameters:

none

Return Parameters:

type	Description
uint8_t	Current crystal trim value.

Notes :

5.1.9 dwt_setlocaldataptr

```
int dwt_setlocaldataptr(unsigned int index);
```

The DW3000 API uses an internal data structure to hold some local state data. The device driver is able to handle multiple DW3000 devices by using an array of those structures, as set by the #define of the DWT_NUM_DW_DEV pre-processor symbol. This [dwt_setlocaldataptr\(\)](#) API function sets the local data structure pointer to point to the element in the local array as given by the index.

Parameters :

type	name	description
unsigned int	index	This selects the array element to point to. Must be within the array bounds, i.e. < DWT_NUM_DW_DEV.

Return Parameters :

type	description
int	Return value can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes :

The local device static data is an array to support multiple devices, e.g. in testing applications and platforms. This function selects which element of the array is being accessed. For example, if two DW3000 devices are controlled in your application then this function should be called before accessing either of the devices to configure the local structure pointer. To handle multiple devices the low-level SPI access function also needs to be set to talk to the correct device.

5.1.10 dwt_otprevision

```
uint8_t dwt_otprevision(void);
```

This function returns OTP revision as read during the call to [dwt_initilise\(\)](#). This location is suggested for customer programming, (and is used in Decawave's evaluation board products to identify different/changes in usage of the OTP area).

Parameters :

none

Return Parameters:

type	description
uint8_t	8-bit OTP revision value.

Notes:**5.1.11 dwt_softreset**

```
void dwt_softreset(void);
```

This function performs a software-controlled reset of the transceiver IC. All of the IC configurations will be reset back to default. Please refer to the User Manual [2] for details of IC default configuration register values. **The SPI rate must be set to <= 7 MHz before a calling this API.**

Parameters:

none

Return Parameters:

none

Notes:

This function is used to reset the IC, e.g. before applying new configuration to clear all of the previously set values. After reset the IC will be in the INIT state, and all of the registers will have default values. Any values programmed into the always on (AON) low-power configuration array store will also be cleared.

Note: The RSTn pin can also be used to reset the device. Host microprocessor can use this pin to reset the device instead of calling [dwt_softreset\(\)](#) function. The pin should be driven low (for 10 ns) and then left in open-drain mode. **RSTn pin should never be driven high.**

5.1.12 dwt_checkidlerc

```
uint8_t dwt_checkidlerc(void);
```

This function checks if the device is in IDLE_RC state by reading the SYS_STATUS register and checking for the IDLE_RC event to be set.

Parameters:

none

Return Parameters:

type	Description
------	-------------

uint8_t	Return value is 1 if device is in IDLE_RC state and 0 otherwise.
---------	--

Notes:

It is advised to call this function before calling [dwt_initialise\(\)](#) in order to check that the device is in the correct state before initializing.

Example code:

```
/* Reads and validate device ID returns DWT_ERROR if it does not match
expected else DWT_SUCCESS */
int err;

if ((err=dwt_check_dev_id())==DWT_SUCCESS)
{
    printf("DEV ID OK\n");
}
else
{
    printf("DEV ID FAILED\n");
}
```

5.1.13 dwt_initialise

```
int dwt_initialise(int mode);
```

The [dwt_initialise\(\)](#) is function which initialises the DW3000 transceiver and sets up values in an internal static data structure used within the device driver functions. This static data is private data used within the device driver implementation.

Parameters:

type	name	description
int	mode	This is a bitmask which specifies which configuration to load from OTP as part of initialisation Table 1 shows the values of individual bit fields

Return Parameters:

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

This [dwt_initialise\(\)](#) function is the first function that should be called to initialise the device, e.g. after the power has been applied. It reads the device ID to verify the IC is one supported by this software (e.g. for DW3000 the 32-bit device ID value is 0xDECA03xx).

This [dwt_initialise\(\)](#) function also reads some data from OTP:

- LDO tune and crystal trim values, which are applied directly if they are valid.
- Device's Part ID and Lot ID which are stored in driver's local structure for future access.

If the DWT_ERROR is returned by [dwt_initialise\(\)](#) then further configuration and operation of the IC is not advised, as the IC will not be functioning properly.

Table 1: Config parameter to dwt_initialise() function

Mode	Mask Value	Description
DWT_DW_INIT	0x0	Do not load any OTP values, also leave the device in INIT state.
DWT_READ_OTP_PID	0x10	Reads part ID from OTP, and stores it in internal structure. The dwt_getpartid() API can then be used to access it.
DWT_READ_OTP_LID	0x20	Reads lot ID from OTP, and stores it in internal structure. The dwt_getlotid() API can then be used to access it.
DWT_READ_OTP_BAT	0x40	Reads reference (measured @ 1.8 V) raw Voltage value from OTP, and stores it in internal structure. The dwt_geticrefvolt() API can then be used to access it.
DWT_READ_OTP_TMP	0x80	Reads reference (measured @ 23 °C) raw Temperature value from OTP, and stores it in internal structure. The dwt_geticreftemp() API can then be used to access it.

Notes:

For more details of the OTP memory programming please refer to section [dwt_otpwriteandverify\(\)](#). **Programming OTP memory is a one-time only activity, any values programmed in error cannot be corrected. Also, please take care when programming OTP memory to only write to the designated areas – programming elsewhere may permanently damage the IC's ability to function normally.**

Example 1: - On power up

```
//Initialise DW3000 device, load OTP values and
dwt_initialise(DWT_READ_OTP_PID | DWT_READ_OTP_LID | DWT_READ_OTP_BAT |
DWT_READ_OTP_TMP)
```

5.2 Configure APIs

5.2.1 dwt_configure

```
void dwt_configure(dwt_config_t *config);
```

This function is responsible for setting up the channel configuration parameters for use by both the transmitter and the receiver. The settings are specified by the [dwt_config_t](#) structure passed into the function, see notes below. (Note also there is a separate function [dwt_setplenfine\(\)](#) for setting certain TX parameters. This is described in section 5.2.3 below). The device will be put into IDLE state after the configuration of the PLL.

Parameters:

type	name	description
dwt_config_t*	config	This is a pointer to the configuration structure, which contains the device configuration data. Individual fields are described in detail in the notes below.

```
typedef struct
{
    uint8_t chan ;           //!< channel number {5, 9}
    uint8_t txPreambleLength; //!< DWT_PLEN_64..DWT_PLEN_4096
    uint8_t rxPAC ;         //!< Acquisition Chunk Size (Relates
to RX                       // preamble length)

    uint8_t txCode ;        //!< TX preamble code
    uint8_t rxCode ;        //!< RX preamble code
    uint8_t sfdType ;       //!< SFD type (0 - short IEEE 8 standard
                            // 1 - DW 8, 2 - DW 16, 3 - 4z
                            // use non-std SFD for better performance

    uint8_t dataRate ;      //!< Data Rate {DWT_BR_850K or DWT_BR_6M8}
    uint8_t phrMode ;       //!< PHR mode:
                            // 0x0 - standard DWT_PHRMODE_STD
                            // 0x3 - extended frames DWT_PHRMODE_EXT

    uint8_t phrRate ;       //!< PHR rate {0x0 - standard
                            // DWT_PHRRATE_STD, 0x1 - at datarate
                            // DWT_PHRRATE_DTA}

    uint16_t sfdTO ;        //!< SFD timeout value (in symbols)
    uint8_t stsMode ;       //!< STS mode (no STS, before PHR or //
                            // after data)

    dwt_sts_lengths_e stsLength ; //!< STS length
    uint8_t pdoaMode ;      //!< pdoa mode
} dwt_config_t ;

typedef enum
{
    DWT_STS_LEN_32  =0,
    DWT_STS_LEN_64  =1,
    DWT_STS_LEN_128 =2,
    DWT_STS_LEN_256 =3,
    DWT_STS_LEN_512 =4,
    DWT_STS_LEN_1024=5,
    DWT_STS_LEN_2048=6
}dwt_sts_lengths_e;
```

Return Parameters:

none

Notes:

The [*dwt_configure\(\)*](#) function should be used to configure the IC's channel (TX/RX) parameters before receiver enable or before issuing a start transmission command. It can be called again to change configurations as needed, however before using [*dwt_configure\(\)*](#) the IC should be returned to idle mode using the [*dwt_forcetrxoff\(\)*](#) API call.

The [*config*](#) parameter points to a [*dwt_config_t*](#) structure that has various fields to select and configure different parameters within the IC. The fields of the [*dwt_config_t*](#) structure are identified individually described below:

Fields	Description of fields within the <i>dwt_config_t</i> structure
<i>chan</i>	The <i>chan</i> parameter sets the UWB channel number, (defining the centre frequency and bandwidth). The supported channels are 5, and 9.
<i>txCode</i> and <i>rxCode</i>	The <i>txCode</i> and <i>rxCode</i> parameters select the preamble codes to use in the transmitter and the receiver – these are generally both set to the same values. For correct operation of the device, the selected preamble code should follow the rules of IEEE 802.15.4-2015 [3] UWB with respect to which codes are allowed in the particular channel and PRF configuration, this is shown in Table 2 below. The code will also define the PRF (pulse repetition frequency) used.
<i>sfdType</i>	The <i>sfdType</i> parameter enables the use of one of 4 possible SFD (Start Frame Delimiter) sequences. The supported values are: 0 - short IEEE 8-bit standard, 1 - DW 8-bit, 2 - DW 16-bit, 3 - 4z BPRF) DW 8 and 16 bit sequences, which Decawave has found to be more robust than that specified in the IEEE 802.15.4 standard, give improved performance.
<i>dataRate</i>	The <i>dataRate</i> parameter specifies the data rate to be one of 850kbps or 6800kbps, via symbolic definitions DWT_BR_850K and DWT_BR_6M8.
<i>txPreambleLength</i>	The <i>txPreambleLength</i> parameter specifies preamble length which has a range of values given by symbolic definitions: DWT_PLEN_4096, DWT_PLEN_2048, DWT_PLEN_1536, DWT_PLEN_1024, DWT_PLEN_512, DWT_PLEN_256, DWT_PLEN_128, DWT_PLEN_64, DWT_PLEN_32. Table 3 gives recommended preamble sequence lengths to use depending on the data rate.
<i>rxPAC</i>	<p>The <i>rxPAC</i> parameter specifies the Preamble Acquisition Chunk size to use. Allowed values are DWT_PAC8, DWT_PAC16, DWT_PAC32 or DWT_PAC4. Table 4 below gives the recommended PAC size to use in the receiver depending on the preamble length being used in the transmitter. PAC size is specified in preamble symbols, which are approximately 1 μs each.</p> <p>Note: The <i>dwt_setsniffmode()</i> and <i>dwt_setpreambledetecttimeout()</i> API functions use PACs as the unit to specify the time the receiver is on looking for preamble.</p>
<i>phrMode</i>	The <i>phrMode</i> parameter selects between either the standard or extended PHR mode is set, either DWT_PHRMODE_STD for standard length frames 5 to 127 octets long or non-standard DWT_PHRMODE_EXT allowing frames of length 5 to 1023 octets long.
<i>phrRate</i>	The <i>phrRate</i> parameter selects between either using the standard 850 kbps rate for PHR symbols or using a higher rate – same as the data rate

Fields	Description of fields within the <i>dwt_config_t</i> structure
<i>sfdTO</i>	The <i>sfdTO</i> parameter sets the SFD timeout value. The purpose of the SFD detection timeout is to recover from the occasional false preamble detection events that may occur. By default, this value is 4096 + 64 + 1 symbols, which is just longer the longest possible preamble and SFD sequence. This is the maximum value that is sensible. When it is known that a shorter preamble is being used then the value can be reduced appropriately. The function does not allow a value of zero. (If a 0 value is selected the default value of 4161 symbols (<i>DWT_SFDTOC_DEF</i>) will be used). The recommended value is preamble length + 1 + SFD length – PAC size.
<i>stsMode</i>	The <i>stsMode</i> parameter sets one of four possible STS modes: no STS, STS before PHR, STS after data, or no data mode.
<i>stsLength</i>	The <i>stsLength</i> parameter specifies STS length. The API supports the lengths defined by the <i>dwt_sts_lengths_e</i> .
<i>pdoaMode</i>	The <i>pdoaMode</i> parameter configures one of three possible PDOA modes: no PDOA, mode 1 (PDOA is calculated between Ipatov POA and STS POA), mode 3 (PDOA is calculated between two STS blocks)

The *dwt_configure()* function does not error check the input parameters unless the DWT_API_ERROR_CHECK code switch is defined. If this is defined, it will assert in case an error is detected. It is up to the developer to ensure that the assert macro is correctly enabled in order to trap any error conditions that arise. If DWT_API_ERROR_CHECK switch is not defined, error checks are not performed.

NOTE: SFD timeout cannot be set to 0; if a zero value is passed into the function the default value will be programmed. To minimise power consumption in the receiver, the SFD timeout of the receiving device, *sfdTO* parameter, should be set according to the TX preamble length of the transmitting device. As an example, if the transmitting device is using 128 preamble length, an SFD length of 8 and a PAC size of 8, the corresponding receiver should have *sfdTO* parameter set to 129 (128 + 1 + 8 - 8).

Table 2: supported UWB channels and recommended preamble codes

Channel number	Preamble Codes (16 MHz PRF)	Preamble Codes (64 MHz PRF)	Preamble Codes (SCP)
5, 9	3, 4	9, 10, 11, 12	25, 26, 27, 28, 29

In addition to the preamble codes in shown in Table 2 above, for 64 MHz PRF there are eight additional preamble codes, (13 to 16, and 21 to 24), available for use on all channels. These should only be selected as part of implementing dynamic preamble selection (DPS). Please refer to the IEEE 802.15.4 standard [3] for more details of the dynamic preamble selection technique.

The preamble sequence used on a particular channel is the same at all data rates, however its length, (i.e. the number of symbol times for which it is repeated), has a significant effect on the operational range. Table 3 gives some recommended preamble sequence lengths to use depending on the data rate. In general, a longer preamble gives improved range performance and better first path time of arrival information while a shorter preamble gives a shorter air time and saves power. When operating a low data rate for long range, then a long preamble is needed to achieve that range. At higher data rates the operating range is naturally shorter so there is no point in sending an overly long preamble as it wastes time and power for no added range advantage.

Table 3: Recommended preamble lengths

Data Rate	Recommended preamble sequence length
6.8Mbps	32, 64, 128 or 256
850kbps	256, or higher

The preamble sequence is detected by cross-correlating in chunks which are a number of preamble symbols long. The size of chunk used is selected by the PAC size configuration, which should be selected depending on the expected preamble size. A larger PAC size gives better performance when the preamble is long enough to allow it. But if the PAC size is too large for the preamble length then receiver performance will reduce or fail to work at the extremes – (e.g. a PAC of 32 will never receive frames with just 32 preamble symbols). Table 4 below gives the recommended PAC size configuration to use in the receiver depending on the preamble length being used in the transmitter.

Table 4: Recommended PAC size

Expected preamble length of frames being received	Data Rate	Recommended PAC size
32	6.81 Mb/s	4
≥ 64	6.81 Mb/s	8
≥ 128	850 kb/s	16

Notes of STS modes:

This function configures the STS mode (defined in Table 5). When STS modes 1 or 2 are configured, the IC will transmit a STS after the SFD (in Mode 1) or after data (in Mode 2). The STS PRF will match the Ipatov. The API supports a number of STS length configurations as specified by `dwt_sts_lengths_e`. Prior to transmission of STS, a 128-bit IV (initial value), via counter register, generates a 128-bit “NONCE” value which with the 128-bit key value feeds into the CPRNG block (pseudo-random number generator block) to generate codes for each pair of preamble symbols, see Figure 5. The supported PRF is 64 MHz.

A user is expected to either set a unique key and IV e.g. per ranging/communication session is started between a number of devices, or keep the same key for some time but update the IV (e.g. the low x

bits) to keep session secure. Optionally Super Deterministic Codes can be used, this means that the programming of STS key and IV is not necessary.

Table 5: *stsMode* parameter to *dwt_configure()* function

Mode	Value	Description
DWT_STS_MODE_OFF	0x0	The IC is not configured to use STS.
DWT_STS_MODE_1	0x1	The IC is configured to use STS mode 1, i.e. the STS comes before data
DWT_STS_MODE_2	0x2	The IC is configured to use STS mode 2, i.e. the STS comes after data
DWT_STS_MODE_SDC	0x8	The Super Deterministic Codes are used in the STS
DWT_STS_MODE_ND	0x3	Configured to use no data STS mode

The DW3000 supports four STS modes of operation, the packet format of each of these is shown in Figure 4. When the STS modes are used then the IC will transmit a STS preamble, which is a pseudo-random sequence of pulses. This pseudo-random sequence is based on AES128 in counter mode.

The host controller needs to provide the IC with a seed and Initial Value, which can be (re)programmed individually (for this *dwt_configurestskey()* and *dwt_configurestsiv()* APIs are used).

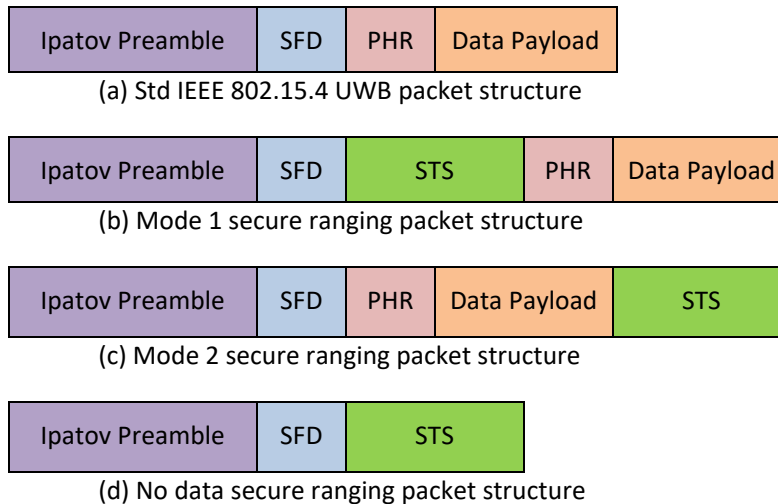

Figure 4: Standard compliant versus secure ranging packet

Assuming the seed is not changed, and the counter is not reset between packets (i.e. by loading a new Initial Value), then a different set of STS symbols will be generated as a result of the natural advancement of the counter. These will be applied to generate the STS that is either used for the transmitted frames, or used in the receiver to correlate with the symbols of the STS in the received frame. Over time the counter will generate 2^{31} - separate 128-bit values before it repeats.

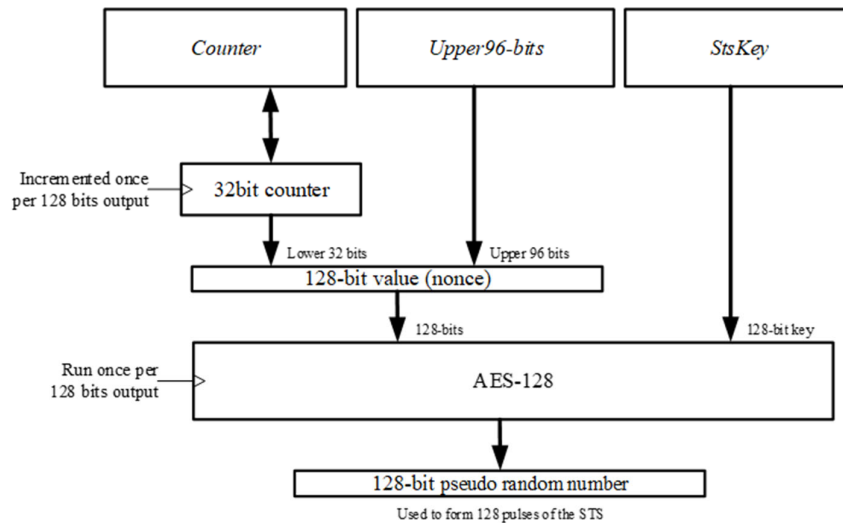

Figure 5: AES in counter mode based CPRNG

See also: [dwt_configuretxrf\(\)](#) for setting certain TX parameters
[dwt_setsniffmode\(\)](#) for setting certain RX (preamble hunt) operating mode.

5.2.2 dwt_restoreconfig

```
void dwt_restoreconfig(void);
```

This function needs to be called after device is woken up from DEEPSLEEP/SLEEP state, to restore the configuration which has not been automatically restored from AON.

Parameters:

none

Return Parameters:

none

Notes:

After a device has woken from a sleep state, this function must be called in order to restore configurations such as LDO configuration, bias tuning and gear table configuration.

5.2.3 dwt_setplenfine

```
void dwt_setplenfine (uint8_t plen);
```

This API function is used to configure frame preamble length, the frame preamble length can be configured in steps of 8, from 16 to 2048 symbols. If a non-zero value is configured, then the TXPSR_PE setting is ignored.

Parameters:

Type	Name	description
uint8_t	plen	Units are 8-symbol blocks, value of 1 is a minimum i.e. 16 symbols, value of 255 is max i.e. 2048 symbols. Value of 0 disables this setting.

Return Parameters:

none

Notes:**5.2.4 dwt_configuretxrf**

```
void dwt_configuretxrf(dwt_txconfig_t *config);
```

The [dwt_configuretxrf\(\)](#) function is responsible for setting up the transmit RF configuration parameters. The values present in the input structure are pulse generator delay (PGdly), transmit output power (power) and pulse generator count (PGcount). The pulse generator delay value sets the width of transmitted pulses effectively setting the output bandwidth. Transmit output power setting assigns a power level to the outputted transmissions. The pulse generator count is a measurement of the pulse generator delay lines – it allows for the calibration of pulse generator delay.

The pulse generator uses delay lines to generate the pulses for the UWB signal. The length of these delay lines determines the length of the pulse (and thus, inversely, the bandwidth of the spectrum). These delay lines are analog (in the sense that they vary across device and temperature). The PGDelay sets the length of the lines to explicitly set the delay.

Parameters:

type	name	description
dwt_txconfig_t*	config	This is a pointer to the TX parameters configuration structure, which contains the device configuration data. Individual fields are described in detail below.

```
typedef struct
{
    uint8_t      PGdly;           //Pulse generator delay value
    uint32_t     power;           //the TX power - 4 bytes
    uint16_t     PGcount;        //Pulse generator count value
} dwt_txconfig_t ;
```

Return Parameters:

none

Notes:

This function can be called any time and it will configure the IC's TX spectrum parameters. The [config](#) parameter points to a [dwt_txconfig_t](#) structure (shown above) with fields to configure the pulse generator delay ([PGdly](#)), TX power ([power](#)), and pulse generator count ([PGCount](#)). Recommended

values for *PGdly* are given in Table 6 below. (this may be called to adjust power and bandwidth as temperature fluctuates)

Table 6: PGdly recommended values

TX Channel	recommended PGdly value
5	0x34
9	0x34

Table 7: TX power recommended values

TX Channel	recommended TX power value
5	0xfdfdfdfd
9	0xfefefefe

Table 8: dwt_txconfig_t parameter: *power* function

<i>power</i> byte index	Byte name	Function
0	DATA_PWR	Power level applied during the transmission of the data portion of the frame
1	PHR_PWR	Power level applied during the transmission of the PHR portion of the frame
2	SHR_PWR	Power level applied during the transmission of the preamble and SFD portions of the frame
3	STS_PWR	Power level applied during the transmission of the STS preamble portion of the frame

Table 7 above gives the recommended TX power settings. The use of the individual octet values of the 4-byte TX power array are specified in Table 8, for further details of the power values please refer to the User Manual [2].

NB: The values in Table 7 have been chosen to suit Decawave's evaluation boards. For other hardware designs the values here may need to be changed as part of the transmit power calibration activity, and there is a location in OTP memory where the calibrated values can be stored and then read and programmed from the application code. Please consult with Decawave's applications support team for details of transmit power calibration procedures and considerations.

5.2.5 dwt_setrxantennadelay

```
void dwt_setrxantennadelay(uint16_t antennaDelay);
```

This function sets the RX antenna delay. The [antennaDelay](#) value passed is programmed into the RX antenna delay register. This needs to be set so that the RX timestamp is correctly adjusted to account for the time delay between the antenna and the internal digital RX timestamp event. This is determined by a calibration activity. Please consult with Decawave applications support team for details of antenna delay calibration procedures and considerations.

Parameters:

type	name	description
uint16_t	antennaDelay	The delay value is in DWT_TIME_UNITS (15.65 picoseconds ticks)

Return Parameters:

none

Notes:

This function is used to program the RX antenna delay.

5.2.6 dwt_settxantennadelay

```
void dwt_settxantennadelay(uint16_t antennaDelay);
```

This function sets the TX antenna delay. The [antennaDelay](#) value passed is programmed into the TX antenna delay register. This needs to be set so that the TX timestamp is correctly adjusted to account for the time delay between internal digital TX timestamp event and the signal actually leaving the antenna. This is determined by a calibration activity. Please consult with Decawave applications support team for details of antenna delay calibration procedures and considerations.

Parameters:

type	name	description
uint16_t	antennaDelay	The delay value is in DWT_TIME_UNITS (15.65 picoseconds ticks)

Return Parameters:

none

Notes:

This function is used to program the TX antenna delay.

5.2.7 dwt_configurestskey

```
void dwt_configurestskey ( dwt_sts_cp_key_t* pStsKey);
```

This function can be used to configure the STS 128-bit AES key value. The default value is [31:0] C9A375FA, [63:32] 8DF43A20, [95:64] B5E5A4ED, [127:96] 0738123B

Parameters:

Type	Name	description
dwt_sts_cp_key_t*	pStsKey	Pointer to the structure of dwt_sts_cp_iv_t type containing the 128-bit AES key for STS, (i.e. 16 bytes, LSB comes first – to write default value in: pStsKey [0] would be 0xFA, pStsKey [1] would be 0x75, etc.)

```
typedef struct
{
    uint32_t    key0;
    uint32_t    key1;
    uint32_t    key2;
    uint32_t    key3;
} dwt_ata_cp_key_t;
```

Return Parameters:

none

Notes:**5.2.8 dwt_configuresiv**

```
void dwt_configuresiv (dwt_sts_cp_iv_t* pStsIv);
```

This function is used to configure the STS 128-bit initial value. The default value is 1, i.e. the IC reset value is 1. A value of all 0 is invalid and the IC will automatically detect this condition and set it to 1.

Parameters:

Type	Name	description
dwt_sts_cp_iv_t*	pStsIv	Pointer to the structure of dwt_sts_cp_iv_t type containing the 128-bit initial value for STS. (i.e. 16 bytes, LSB comes first)

```
typedef struct
{
    uint32_t    iv0;
    uint32_t    iv1;
    uint32_t    iv2;
    uint32_t    iv3;
} dwt_sts_cp_iv_t;
```

Return Parameters:

none

Notes:

In order to make the counter more random its initial state (IV) is seeded from time to time (updating frequency should be less than its period). For security reasons the key should also be updated at the same time (with a different value).

The values it generates act as a nonce which together with the supplied key are used to generate the STS.

5.2.9 dwt_configurestsmode

```
void dwt_configurestsmode(uint8_t stsMode);
```

This function configures STS mode (e.g. DWT_STS_MODE_OFF, DWT_STS_MODE_1, etc.) The dwt_configure() should be called prior to this to configure other parameters.

Parameters:

type	name	description
uint8_t	stsMode	The STS mode that the device should be configured for.

Return Parameters:

none

Notes:

For more information on the input parameter, please see Table 5: [stsMode](#) parameter to dwt_configure() function.

5.2.10 dwt_configurestsloadiv

```
void dwt_configurestsloadiv (void);
```

This function is used to load the IV and KEY initial value into the STS AES block.

Parameters:

none

Return Parameters:

none

Notes:

If this function is called when reloading the counter with a previously set IV, without changing the key, then the generated STS sequence will potentially be repeating in a predictable way. While this may be useful in some testing scenarios, it could be a security risk if it were done in normal operation, where any reloading of the counter should be accompanied by a new key load also.

5.2.11 dwt_configuresfdtype

```
void dwt_configuresfdtype(uint8_t sfdType);
```

This function configures SFD type only: e.g. IEEE 4a - 8, DW-8, DW-16, or IEEE 4z -8 (binary). The dwt_configure() should be called prior to this to configure other parameters.

Parameters:

type	name	description
uint8_t	sfdType	This value is used to assign the SFD type used when configuring the device. Please see Table 9 for more information.

Table 9: *sfdType* parameter to *dwt_configuresfdtype()* function

Mode	Value	Description
DWT_SFD_IEEE_4A	0x0	IEEE 8-bit ternary
DWT_SFD_DW_8	0x1	Decawave / Qorvo 8-bit SFD
DWT_SFD_DW_16	0x2	Decawave / Qorvo 16-bit SFD
DWT_SFD_IEEE_4Z	0x3	IEEE 8-bit binary (4z)

Return Parameters:

none

5.2.12 dwt_setleds

```
void dwt_setleds(uint8_t mode);
```

This is used to set up Tx/Rx GPIOs which are then used to control (for example) LEDs. This is not completely IC dependent; it requires that LEDs are connected to the GPIO lines.

Parameters:

type	name	description
uint8_t	mode	<p>This is a bit field value interpreted as follows:</p> <ul style="list-style-type: none"> - bit 0: set to 1 to enable LEDs, 0 to disable them. - bit 1: set to 1 to make LEDs blink once on init. This is only valid if bit 0 is set (enable LEDs). - Bits 2 to 7: Reserved.

Return Parameters:

none

Notes:

For more information on GPIO control and configuration please consult the User Manual [2] and Data Sheet [1].

5.2.13 dwt_setlnapamode

```
void dwt_setlnapamode(int lna_pa)
```

This is used to enable GPIO for external LNA or PA functionality – HW dependent, consult the User Manual [2]. This can also be used for debug as enabling TX and RX GPIOs is can help monitoring the IC's activity.

Parameters:

type	name	description
int	lna_pa	<p>This parameter is treated as a bit field.</p> <p>If bit 0 is set (DWT_LNA_ENABLE), it will enable LNA functionality.</p> <p>If bit 1 is set (DWT_PA_ENABLE), it will enable PA functionality.</p> <p>If bit 2 is set (DWT_TXRX_EN), it will enable RX/TX sampling on GPIOs 0 & 1.</p> <p>To disable LNA/PA functionality, set bits 0 and 1 to 0.</p>

Return Parameters:

none

Notes:

Enabling PA functionality requires that fine grain TX sequencing is deactivated. This can be done using the `dwt_setfinegraintxseq` API function.

For more information on GPIO control and configuration please consult the User Manual [2] and Data Sheet [1].

5.2.14 dwt_generatecrc8

```
uint8_t dwt_generatecrc8 (const uint8_t* byteArray, int flen, uint8_t crcRemainderInit);
```

This function is used to generate 8-bit CRC to send as part of SPI write transaction when the IC is configured for SPI CRC check mode.

Parameters:

Type	Name	description
uint8_t*	byteArray	This array supplies the bytes for which to calculate the CRC.
int	flen	Length of the <i>byteArray</i> parameter in bytes
uint8_t	crcRemainderInit	The remainder is the CRC, also it is initially set to the initialisation value for CRC calculation.

Return Parameters:

type	Description
------	-------------

uint8_t	The calculated 8-bit CRC function.
---------	------------------------------------

Notes:

It is possible to calculate CRC for two separate blocks (that will be sent as one contiguous SPI transaction) by calling the [dwt_generatecrc8\(\)](#) function twice, once for each; setting the first `crcRemainderInit` parameter to the configured CRC seed (zero by default), and the second `crcRemainderInit` parameter to the CRC value returned from the first call to the [dwt_generatecrc8\(\)](#) function.

5.2.15 dwt_enablespicrccheck

```
void dwt_enablespicrccheck (dwt_spi_crc_mode_e crc_mode, dwt_spierrcb_t spireaderr_cb);
```

This function can be used to enable or disable the SPI CRC check in the IC.

Parameters:

Type	Name	description
dwt_spi_crc_mode_e	crc_mode	If set to DWT_SPI_CRC_MODE_WR then SPI CRC checking will be performed in DW3000 on each SPI write. The last byte of the SPI write transaction needs to be the 8-bit CRC, if it does not match the one calculated by DW3000 SPI, a CRC ERROR event will be set in the status register (SPICRC bit of SYS_STATUS_LO register).
dwt_spierrcb_t	spireaderr_cb	This parameter needs to contain the callback function pointer which will be called when a SPI read error is detected (when the DW3000 generated CRC does not match the one calculated by dwt_generatecrc8 following the SPI read transaction).

Return Parameters:

none

Notes:

The [crc_mode](#) parameter is used to select the CRC mode to be used. The following table shows all the available options in the [dwt_spi_crc_mode_e](#) enum that is used to contain the argument:

Table 10: Valid crc_mode options

Parameter	Value	Description
DWT_SPI_CRC_MODE_NO	0	No CRC
DWT_SPI_CRC_MODE_WR	1	Enable SPI CRC check on write functions.
DWT_SPI_CRC_MODE_WRRD	2	Enable SPI CRC on both write and read operations.

During normal SPI mode the SPICRC bit of the SYS_STATUS_LO register will be asserted. When using SPI CRC check mode this will only be asserted if there is a mismatch between the CRC byte calculated by the IC and the one sent in the SPI write transaction.

5.2.16 dwt_configmrxlut

```
void dwt_configmrxlut(int channel);
```

This function sets the default values of the lookup tables depending on the channel selected.

Parameters :

Type	Name	description
int	channel	This is the channel: 5 or 9.

Return Parameters :

none

Notes :

The lookup table contains the desired front-end settings for the chosen level of noise dithering. Different settings will apply for channel 5 or channel 9. The seven registers starting at DGC_DGC_LUT_0_CFG and ending at DGC_DGC_LUT_6_CFG are populated as follows depending on the channel given:

Table 11: Channel 5 Lookup Table Configuration

Gain	LUT Configuration Register Value
Max Gain, NF	0x1c0fd
MaxGain - 12dB, NF + 6dB	0x1c43e
MaxGain - 17dB, NF + 10dB	0x1c6be
MaxGain - 28dB, NF + 16dB	0x1c77e
MaxGain - 32dB, NF + 23dB	0x1cf36
MaxGain - 37dB, NF + 29dB	0x1cfb5
MaxGain - 39dB, NF + 30dB	0x1cff5

Table 12: Channel 9 Lookup Table Configuration

Gain	LUT Configuration Register Value
Max Gain, NF	0x2a8fe
Max Gain-12dB, NF+4dB	0x2ac36
Max Gain-20dB, NF+10dB	0x2a5fe
Max Gain-24dB, NF+16dB	0x2af3e
Max Gain-30dB, NF+20dB	0x2af7d
Max Gain-33dB, NF+24dB	0x2afb5
Max Gain-40dB, NF+28dB	0x2afb5

5.2.17 dwt_enablegpioclocks

```
void dwt_enablegpioclocks(void);
```

This function enables the GPIO clocks on the IC. GPIO clocks are required to ensure correct GPIO operation.

Parameters:

none

Return Parameters:

none

Notes:

An example of how this API can be used is included in the API package [5]. Also, please see [Example 13a: Use of DW3000 GPIO lines](#).

5.2.18 dwt_pgf_cal

```
int dwt_pgf_cal(int ldoen);
```

This function sets up the PGF calibration to be run. PGF calibration is run as part of [dwt_run_pgfcalf\(\)](#). This is needed prior to reception of any frames/packets.

Parameters:

Type	Name	description
------	------	-------------

int	ldoen	This signifies whether the PGF LDOs should be enabled when running the function. A '1' signifies that PGF LDOs will be turned on and a '0' signifies that they will not be turned on.
-----	-------	---

Return Parameters:

An int value is returned which gives the result of the PGF calibration that is carried out as part of this functions operation.

Notes:

This function is run as part of the final step of [dwt_configure\(\)](#).

5.2.19 dwt_run_pgfcsl

```
int dwt_run_pgfcsl(void);
```

This function runs the PGF calibration. It is usually called by [dwt_pgfcsl\(\)](#). This is needed prior to reception of any frames/packets.

Parameters:

none

Return Parameters:

An int value is returned which gives the result of the PGF calibration.

Notes:**5.2.20 dwt_setdwstate**

```
void dwt_setdwstate(int state);
```

This function can place DW3000 into IDLE/IDLE_PLL or IDLE_RC mode when it is not actively in TX or RX.

Parameters:

type	name	description
int	state	DWT_DW_IDLE (1) to put DW3000 into IDLE/IDLE_PLL state. DWT_DW_INIT (0) to put DW3000 into INIT_RC state. DWT_DE_IDLE_RC (2) to put DW3000 into IDLE_RC state

Return Parameters:

none

Notes:

5.3 TX/RX and Timestamp APIs

5.3.1 dwt_writetxdata

```
int dwt_writetxdata(uint16_t txBufferLength, uint8_t *txBuffer, uint16_t txBufferOffset);
```

This function is used to write the TX message data into the device's internal TX buffer (max size is 1024 bytes).

Parameters:

type	name	description
uint16_t	txBufferLength	This is the total length to write into the TX buffer, it can include the space for the two-byte CRC but it does not have to. The device will automatically put a two-byte CRC in the last two bytes of the TX data it is sending. The length of data to transmit is specified by the txFrameLength parameter in dwt_writetxctrl()
uint8_t*	txBuffer	Pointer to the buffer containing the data to send.
uint16_t	txBufferOffset	This specifies an offset in the device's internal TX buffer at which to start writing data.

Return Parameters:

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

This function writes the specified size of [txBuffLength](#) bytes from the memory, pointed to by the [txBuffBytes](#) parameter, into the device's internal transmit data buffer, starting at the specified offset ([txBufferOffset](#)). During the transmission, the device will automatically add the two CRC bytes to complete the TX frame to its [txFrameLength](#) as specified by the [txFrameLength](#) parameter in [dwt_writetxctrl\(\)](#).

NOTE: standard PHR mode allows frames of up to 127 bytes. For longer lengths non-standard PHR mode DWT_PHRMODE_EXT needs to be set in the [phrMode](#) configuration passed into the [dwt_configure\(\)](#) function.

The [dwt_writetxdata\(\)](#) function checks that the sum of [txBufferLength](#) and [txBufferOffset](#) is less than the max (1024 bytes) internal TX buffer length to avoid messing with IC's other registers and memory. If such an error occurs, the write is not performed and the function returns DWT_ERROR. Otherwise, the functions returns DWT_SUCCESS.

If DWT_API_ERROR_CHECK code switch is defined, the function will perform additional checks on input parameters. If an error is detected, the function will assert. It is up to the developer to ensure that the assert macro is correctly enabled in order to trap any error conditions that arise.

Example code:

Typical usage is to write the data, configure the frame control with starting buffer offset and frame length and then enable transmission as follows:

```
dwt_writetxdata(fLength,dataBuffPtr,0); // write the frame data at offset 0
dwt_writetxfctrl(fLength+2,0,0);      // set the frame control register
dwt_starttx(DWT_START_TX_IMMEDIATE);   // send the frame
```

5.3.2 dwt_writetxfctrl

```
void dwt_writetxfctrl(uint16_t txFrameLength, uint16_t txBufferOffset, uint8_t ranging);
```

This function is used to configure the TX frame control register.

Parameters:

type	Name	description
uint16_t	txFrameLength	This is the total frame length, including the two-byte CRC.
uint16_t	txBufferOffset	This specifies an offset in the device's internal TX Buffer at which to start writing data.
uint8_t	ranging	This specifies whether the TX frame is a ranging frame or not, i.e. whether the ranging bit is set in the PHY header (PHR) of the frame. A value of 1 sets the ranging bit the PHR of the outgoing frame, while a value of 0 will clear it.

Return Parameters:

none

Notes:

This function configures the TX frame control register parameters, namely the length of the frame and the offset in the IC's transmit data buffer where the data starts. It also controls whether the ranging bit is set in the frame's PHR.

The ranging bit identifies a frame as a ranging frame. This has no operational effect on the IC, but in some receiver implementations, it might be used to enable hardware or software associated with time stamping the frame. In the IC's receiver, the time stamping does not depend or use the ranging bit in the received PHR. The status of the ranging bit in received frames is reported by the `cbRxOk` function (if enabled) in the `rx_flags` element of its `dwt_cb_data_t` structure parameter. See the [dwt_isr\(\)](#) and the [dwt_setcallbacks\(\)](#) functions.

The [dwt_writetxfctrl\(\)](#) function does not error check the [txFrameLength](#) and the [txBufferOffset](#) input parameter unless the `DWT_API_ERROR_CHECK` code switch is defined. If this is defined it will assert if an error is detected. It is up to the developer to ensure that the assert macro is correctly enabled in order to trap any error conditions that arise.

Example code:

Typical usage is to write the data, configure the frame control with starting buffer offset and frame length and then enable transmission as follows:

```
dwt_writetxdata(fLength,dataBuffPtr,0); // write the frame data at offset 0
dwt_writetxfctrl(fLength+2,0,0);      // set the frame control register
dwt_starttx(DWT_START_TX_IMMEDIATE);   // send the frame
```

5.3.3 dwt_starttx

```
int dwt_starttx(uint8_t mode);
```

This function initiates transmission of the frame. The *mode* parameter is described below.

Parameters:

type	name	description
uint8_t	mode	This is a bit mask defining the operation of the function, see notes and Table 13 below.

Return Parameters:

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

This function is called to start the transmission of a frame.

Transmission begins immediately if the *mode* parameter is DWT_START_TX_IMMEDIATE (0). When the *mode* parameter is DWT_START_TX_DELAYED (1) transmission begins when the system time reaches the *starttime* specified in the call to the *dwt_setdelayedtrxtime()* function described below. The *mode* parameter, with DWT_RESPONSE_EXPECTED set (i.e. 0x2, 0x3, 0x6, 0xA, 0x12 or 0x22), is used to turn the receiver on automatically after the TX event is complete (see table below). This is used to make sure that there are no delays in turning on the receiver and that the IC can start receiving data (e.g. ACK/response) which might come within 12 symbol times from the end of transmission. This function returns 0 for success, or -1 for error. Error means that the transmission has been aborted.

In performing a delayed transmission, if the host microprocessor is late in invoking the *dwt_starttx()* function, (i.e. so that the IC's system clock has passed the specified *starttime* and would have to complete almost a whole clock count period before the start time is reached), then the transmission is aborted (transceiver off) and the *dwt_starttx()* function returns the -1 error indication.

Table 13: Mode parameter to dwt_starttx() function

Mode	Mask Value	Description
DWT_START_TX_IMMEDIATE	0x0	The transmitter starts sending frame immediately.
DWT_START_TX_DELAYED	0x1	The transmitter will start sending a frame once the programmed <i>starttime</i> is reached. See <i>dwt_setdelayedtrxtime()</i> .
DWT_RESPONSE_EXPECTED	0x2	Response is expected, once the frame is sent the transceiver will enter receive mode to wait for response message. See <i>dwt_setrxaftertxdelay()</i> . NOTE all of the START_TX commands can include DWT_RESPONSE_EXPECTED to enable receiver after completed transmission event.

Mode	Mask Value	Description
DWT_START_TX_DLY_REF	0x4	The transmitter will start sending a frame at specified time (which is the sum of time in DREF_TIME register + any time in DX_TIME register, i.e. programmed refftime and starttime) See dwt_setreferencertime() and dwt_setdelayedtrxtime() .
DWT_START_TX_DLY_RS	0x8	The transmitter will start sending a frame at specified time (which is the sum of RX timestamp + any time in DX_TIME register, i.e. last received timestamp and starttime) See dwt_readrxtimestamp32 and dwt_setdelayedtrxtime() .
DWT_START_TX_DLY_TS	0x10	The transmitter will start sending a frame at specified time (which is the sum of TX timestamp + any time in DX_TIME register, i.e. last transmitted timestamp and starttime) See dwt_readtxtimestamp32() and dwt_setdelayedtrxtime() .
DWT_START_TX_CCA	0x20	The transmitter will start sending a frame if no preamble is detected within PTO time (as configured in preamble timeout register see dwt_setpreambledetecttimeout())

Example code:

Typical usage is to write the data, configure the frame control with starting buffer offset and frame length and then enable transmission as follows:

```
dwt_writetxdata(fLength,dataBuffPtr,0); // write the frame data at offset 0
dwt_writetxctrl(fLength,0,0);          // set the frame control register
dwt_starttx(DWT_START_TX_IMMEDIATE);    // send the frame
```

5.3.4 dwt_setdelayedtrxtime

```
void dwt_setdelayedtrxtime (uint32_t starttime);
```

This function sets a send time to use in delayed send or the time at which the receiver will turn on (a delayed receive). This function should be called to set the required send time before invoking the [dwt_starttx\(\)](#) function (above) to initiate the transmission (in [DELAYED_TX](#) mode), or [dwt_rxenable\(\)](#) (below) with [delayed](#) parameter set to 1.

Parameters:

type	name	description
uint32_t	starttime	<p>The TX or RX start time. The 32-bit value is the high 32-bits of the system time value at which to send the message, or at which to turn on the receiver. The low order bit of this is ignored. This essentially sets the TX or RX time in units of approximately 8 ns. (or more precisely $512/(499.2e6*128)$ seconds)</p> <p>For transmission this is the raw transmit timestamp not including the antenna delay, which will be added. For reception it specifies the time to turn the receiver on.</p>

Return Parameters:

none

Notes:

This function is called to program the delayed transmit or receive start time. The *starttime* parameter specifies the time at which to send/start receiving, when the system time reaches this time (minus the times it needs to send preamble etc.) then the sending of the frame begins. The actual time at which the frame's RMARKER transits the antenna (the standard TX timestamp event) is given by the *starttime* + the transmit antenna delay. If the application wants to embed this time into the message being sent it must do this calculation itself.

The system time counter is 40 bits wide, giving a wrap period of 17.20 seconds.

NOTE: Typically, delayed sending might be used to give a fixed response delay with respect to an incoming message arrival time, or, because the application wants to embed the message send time into the message itself. The delayed receive might be used to save power and turn the receiver on only when response message is expected.

Example code:

Typical usage is to write the data, configure the frame control with starting buffer offset and frame length and then enable transmission as follows:

In this example the previous frame's TX timestamp time is used, and a new frame is sent with 100 ms delay from the previous TX time. The full 40-bit representation of 100 ms would be 0x17CDC000, however as the delay register uses high 32 bits only a value of 0x17CDC00 is used.

```
dwt_writetxdata(frameLength,dataBufferPtr,0); // write the frame data at
                                              // offset 0
dwt_writetxctrl(frameLength,0,0);           // set the frame control
                                              // register
dwt_setdelayedtrxtime(0x17CDC00);           // set the 100ms delay
r = dwt_starttx(DWT_START_TX_DLY_TS);       // send the frame at
                                              // appropriate time w.r.t TX
                                              // timestamp

if (r != DWT_SUCCESS)
{
    // start TX was late, TX has been aborted.
    // Application should take appropriate recovery activity
}
```

5.3.5 dwt_setreferencertxtime

```
void dwt_setreferencertxtime (uint32_t reftime);
```

This function sets a reference time to which any delay time is added (as specified by *starttime* in *dwt_setdelayedtrxtime()*). The sum of both will be used as a delayed send time or the time at which the receiver will turn on (a delayed receive). This function should be called to set the required reference time before invoking the *dwt_starttx()* function (above) to initiate the transmission (in *DELAYED_TX* mode), or *dwt_rxenable()* (below) with *delayed* parameter set to 1.

Parameters:

type	name	description
------	------	-------------

uint32_t	reftime	The TX or RX reference time. The 32-bit value is the high 32-bits of the system time. The low order bit of this is ignored. This essentially sets the TX or RX time in units of approximately 8 ns. (or more precisely $512/(499.2e6 \cdot 128)$ seconds)
----------	---------	---

Return Parameters:

none

Notes:

This function is called to save the delayed transmit or receive reference time. The *reftime* parameter specifies a time at which for example a “sync or beacon” frame was sent, and which will be used as a reference w.r.t. which other frames will be sent/received.

The system time counter is 40 bits wide, giving a wrap period of 17.20 seconds.

NOTE: Typically, delayed sending might be used to give a fixed response delay with respect to an incoming message arrival time, or, because the application wants to embed the message send time into the message itself. The delayed receive might be used to save power and turn the receiver on only when response message is expected.

Example code:

Typical usage is to write the data, configure the frame control with starting buffer offset and frame length and then enable transmission as follows:

In this example consider a reference “sync or beacon” frame is sent at reference time. This time is saved in the reference register. Then, sometime later, we wish to transmit a frame 100 ms after this time, perhaps a next beacon frame. The full 40-bit representation of 100ms would be 0x17CDC0000, however as the reference time register contains only the high 32 bits a value of 0x17CDC00 is used. (The TX timestamp value should be read after a TX done interrupt triggers.)

```
dwt_setreferencetrxtime(dwt_readtxtimestamp32()) ; // read TX time e.g. of
                                                    // sync frame

dwt_writetxdata(frameLength,dataBufferPtr,0); // write the new frame data at
// offset 0
dwt_writetxfctrl(frameLength,0,0);           // set the frame control
// register
dwt_setdelayedtrxtime(0x17CDC00);             // set the delay of 100 ms
r = dwt_starttx(DWT_START_TX_DLY_REF);        // send the frame at
// appropriate time w.r.t. REF
// timestamp

if (r != DWT_SUCCESS)
{
    // start TX was late, TX has been aborted.
    // Application should take appropriate recovery activity
}
```

5.3.6 dwt_readtxtimestamp

```
void dwt_readtxtimestamp(uint8_t* timestamp);
```

This function reads the actual time at which the frame’s RMARKER transits the antenna (the standard TX timestamp event). This time will include any TX antenna delay if programmed via the

[*dwt_settxantennadelay\(\)*](#) API function. The function returns a 40-bit timestamp value in the buffer passed in as the input parameter.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 5 bytes long.) The low order byte is the first element.

Return Parameters:

none

Notes:

This function can be called after the transmission complete event, DWT_INT_TFRS (see [*dwt_isr\(\)*](#) function).

5.3.7 dwt_readtxtimestamplo32

```
uint32_t dwt_readtxtimestamplo32(void);
```

This function returns the low 32-bits of the 40-bit transmit timestamp ([*dwt_readtxtimestamp\(\)*](#)).

Parameters:

none

Return Parameters:

type	description
uint32_t	Low 32-bits of the 40-bit transmit timestamp.

Notes:

This function can be called after the transmission complete event, DWT_INT_TFRS (see [*dwt_isr\(\)*](#) function).

5.3.8 dwt_readtxtimestampphi32

```
uint32_t dwt_readtxtimestampphi32(void);
```

This function returns the high 32-bits of the 40-bit transmit timestamp.

Parameters:

none

Return Parameters:

type	description
uint32_t	High 32-bits of the 40-bit transmit timestamp.

Notes:

This function can be called after the transmission complete event, DWT_INT_TFRS (see [dwt_isr\(\)](#) function).

5.3.9 dwt_readrxtimestamp

```
void dwt_readrxtimestamp(uint8_t* timestamp);
```

This function returns the time at which the frame's RMARKER is received, including the antenna delay adjustments if this is programmed via the [dwt_setrxantennadelay\(\)](#) API function. The function returns a 40-bit value.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 5 bytes long.) The low order byte is the first element.

Return Parameters:

none

Notes:

This function can be called after the frame received event, DWT_INT_RFCG (see [dwt_isr\(\)](#) function). Which means we have a good FCS and a valid timestamp.

5.3.10 dwt_readrxtimestamp_ipatov

```
void dwt_readrxtimestamp_ipatov(uint8_t* timestamp);
```

This function returns the time at which the frame's RMARKER is received, including the antenna delay adjustments if this is programmed via the [dwt_setrxantennadelay\(\)](#) API function, w.r.t. Ipatov CIR. The function returns a 40-bit value.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 5 bytes long.) The low order byte is the first element.

Return Parameters:

none

Notes:

This function can be called after the frame received event, DWT_INT_RFCG (see [dwt_isr\(\)](#) function). Which means we have a good FCS and a valid timestamp.

5.3.11 dwt_readrxtimestamp_sts

```
void dwt_readrxtimestamp_sts(uint8_t* timestamp);
```

This function returns the time at which the frame's RMARKER is received, including the antenna delay adjustments if this is programmed via the [dwt_setrxantennadelay\(\)](#) API function, w.r.t. STS CIR. It is only valid if packet with STS is used, see [dwt_configure\(\)](#). The function returns a 40-bit value.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 5 bytes long.) The low order byte is the first element.

Return Parameters:

none

Notes:

This function can be called after the frame received event, DWT_INT_RFCG (see [dwt_isr\(\)](#) function). Which means we have a good FCS and a valid timestamp.

5.3.12 dwt_readrxtimestampunadj

```
void dwt_readrxtimestampunadj(uint8_t* timestamp);
```

This function returns the raw time at which the frame's RMARKER is received before any CIA first path algorithm adjustments. This will be the high 32-bits of the 40-bit system time.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 4 bytes long.) The low order byte is the first element.

Return Parameters:

none

Notes:

5.3.13 dwt_readrxtimestamplo32

```
uint32_t dwt_readrxtimestamplo32(void);
```

This function returns the low 32-bits of the 40-bit received timestamp ([dwt_readrxtimestamp\(\)](#)).

Parameters:

none

Return Parameters:

type	description
uint32_t	Low 32-bits of the 40-bit received timestamp.

Notes:

This function can be called after the frame received event, DWT_INT_RFCG (see [dwt_isr\(\)](#) function). Which means we have a good FCS and a valid timestamp.

5.3.14 dwt_readrxtimestampphi32

```
uint32_t dwt_readrxtimestampphi32(void);
```

This function returns the high 32-bits of the 40-bit received timestamp ([dwt_readrxtimestamp\(\)](#)).

Parameters:

none

Return Parameters:

type	description
uint32_t	High 32-bits of the 40-bit received timestamp.

Notes:

This function can be called after the frame received event, DWT_INT_RFCG (see [dwt_isr\(\)](#) function). Which means we have a good FCS and a valid timestamp.

5.3.15 dwt_readsystemtime

```
void dwt_readsystemtime(uint8_t* timestamp);
```

This function returns the system time, which is a high 32-bit value of internal 40-bit system counter. The time will only be valid when the IC is in IDLE, TX or RX states because the system timer is running, the timer is disabled in IDLE_RC or SLEEP states.

Parameters:

type	name	description
uint8_t*	timestamp	The pointer to the buffer into which the timestamp value is read. (The buffer needs to be at least 4 bytes long.) The low order byte is the first element. The low order bit will always be 0, as the system timer runs in units of approximately 8 ns. (more precisely $512/(499.2e6*128)$ seconds or 63.8976GHz).

Return Parameters:

none

Notes:

This function can be called to read the system time, when the IC is not in the INIT state.

5.3.16 dwt_readsystemtimestamp32

```
uint32_t dwt_readsystemtimestamp32(void);
```

This function returns the high 32-bits of the 40-bit system time. The LSB will always be 0, as the system timer runs in units of approximately 8 ns. (more precisely $512/(499.2e6*128)$ seconds or 63.8976GHz).

Parameters:

none

Return Parameters:

type	description
uint32_t	High 32-bits of the 40-bit system timestamp.

Notes:

This function can be called to read the IC system time.

5.3.17 dwt_forcetrxoff

```
void dwt_forcetrxoff(void);
```

This function may be called at any time to disable the active transmitter or the active receiver and put the IC back into idle mode (transceiver off).

Parameters:

none

Return Parameters:

none

Notes:

The [*dwt_forcetrxoff\(\)*](#) function can be called any time and it will disable the active transmitter or receiver and put the device in IDLE mode. It issues a transceiver off command to the IC and also

clears status register event flags, so that there should be no outstanding/pending events for processing.

5.3.18 dwt_rxenable

```
int dwt_rxenable(int mode);
```

This function turns on the receiver to wait for a receive frame. The mode parameter is a bit field that allows for selection of number of different RX operations as defined in Table 14. In delayed RX modes the receiver is not turned on until a specific time, set via [dwt_setdelayedtrxtime\(\)](#) and [dwt_setreferencertxtime\(\)](#). This facility is useful to save power in the case when the timing of a response is known. The mode parameter also controls whether the receiver is enabled in case of error, i.e. the delayed RX being late, see notes below for details.

Parameters:

type	name	description
int	mode	This is a bit mask defining the operation of the function, see notes and

Return Parameters:

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

This function can be called any time to enable the receiver. The device should be initialised and have its RF configuration set.

In performing a delayed RX, the host microprocessor can be late in invoking the [dwt_rxenable\(\)](#), (i.e. the system clock has passed the [starttime](#) specified in the call to the [dwt_setdelayedtrxtime\(\)](#) function). The IC has a status flag warning when the specified start time is more than a half period (of the system clock) away. If this is the case, since the clock has a period of over 17 seconds, it is assumed that such a long RX delay is not needed, and the delayed RX is cancelled. The receiver is then either immediately enabled or left off depending on whether DWT_IDLE_ON_DLY_ERR was set in the supplied "mode" parameter, and error flag is returned indicating that the RX on was late. It is up to the application to take whatever remedial action is needed in the case of this late error.

Table 14: Mode parameter to dwt_rxenable function

Mode	Mask Value	Description
DWT_START_RX_IMMEDIATE	0x00	The receiver is activated immediately.
DWT_START_RX_DELAYED	0x01	The receiver, otherwise the receiver will be turned on when the time reaches the starttime set through the dwt_setdelayedtrxtime() .

Mode	Mask Value	Description
DWT_IDLE_ON_DLY_ERR	0x02	This applies only when a delayed start is determined to be late (see notes above). If this is set the receiver will not be enabled in case of a late error, i.e. the IC will be left in IDLE mode. Otherwise, the receiver will be enabled
DWT_START_RX_DLY_REF	0x04	The receiver will be enabled at specified time (which is the sum of time in DREF_TIME register + any time in DX_TIME register, i.e. programmed <i>reftime</i> and <i>starttime</i>) See dwt_setreferencertime() and dwt_setdelayedrxtime() .
DWT_START_RX_DLY_RS	0x08	The receiver will be enabled at specified time (which is the sum of RX timestamp + any time in DX_TIME register, i.e. last received timestamp and <i>starttime</i>) See dwt_readrxtimestamp32 and dwt_setdelayedrxtime() .
DWT_START_RX_DLY_TS	0x10	The receiver will be enabled at specified time (which is the sum of TX timestamp + any time in DX_TIME register, i.e. last transmitted timestamp and <i>starttime</i>) See dwt_readtxtimestamp32() and dwt_setdelayedrxtime() .

5.3.19 dwt_setsniffmode

```
void dwt_setsniffmode(int enable, uint8_t timeOn, uint8_t timeOff);
```

When the receiver is enabled, it begins looking for preamble sequence symbols, and by default, in this preamble-hunt mode the receiver is continuously active. This [dwt_setsniffmode\(\)](#) function allows the configuration of a lower power preamble-hunt mode. In *SNIFF mode* the receiver (RF and digital) is not on all the time, but rather is sequenced on and off with a specified duty-cycle. Using *SNIFF mode* causes a reduction in RX sensitivity depending on the ratio and durations of the on and off periods. See “Low-Power SNIFF mode” chapter in the User Manual [2] for more details.

Parameters:

type	name	description
int	enable	1 to activate SNIFF mode or 2 to enable SNIFF with LDC, 0 to deactivate it and go back to the normal higher-powered reception mode.
uint8_t	timeOn	The receiver ON time in PACs (as per the <i>rxPAC</i> parameter in the dwt_config_t structure parameter to the dwt_configure() API function call). The minimum value for correct operation is 2, giving an on time of 2 PACs. The maximum value is 15. Value of 1 is not allowed and will disable SNIFF mode.
uint8_t	timeOff	The receiver OFF time, expressed in multiples of 128/125 μ s (~1 μ s). Max value is 255.

Return Parameters:

none

Notes:

This function can be called as part of device receiver configuration.

By default (where this API is not invoked) the IC will operate its receiver in normal reception mode. If this API is used to enable SNIFF mode this will be maintained until a reset or it is disabled or re-configured by another call to this [dwt_setsniffmode\(\)](#) function. The SNIFF mode setting is not affected by the [dwt_configure\(\)](#) function.

5.3.20 dwt_setdblrxbuffmode

```
void dwt_setdblrxbuffmode (dwt_dbl_buff_state_e state, dwt_dbl_buff_mode_e mode);
```

This function enables double buffered receive mode.

Parameters:

type	name	description
dwt_dbl_buff_state_e	state	DBL_BUF_STATE_EN to enable, DBL_BUF_STATE_DIS to disable the double buffer RX feature.
dwt_dbl_buff_mode_e	mode	DBL_BUF_MODE_AUTO to enable RX auto re-enable on good frame reception. If mode is DBL_BUF_MODE_MAN, then the host needs to re-enable the receiver following a good frame reception

Return Parameters:

none

Notes:

The [dwt_setdblrxbuffmode\(\)](#) function is used to configure the receiver in double buffer mode. This should not be done when the receiver is enabled. It should be selected in idle mode before the [dwt_rxenable\(\)](#) function is called.

Once the data for the received frame is read, the host should call the [dwt_signal_rx_buff_free\(\)](#) to let the device know the buffer is free again, the host will then be ready to read the next received frame. This is done in the [dwt_isr\(\)](#) which handles the IRQ.

The reader is referred to “Double Receive Buffer” chapter in the User Manual [2] for more details.

5.3.21 dwt_signal_rx_buff_free

```
void dwt_signal_rx_buff_free (void);
```

This function signals to the DW3000 that the host is finished with current buffer and the buffer is free for the DW3000 to receive into again.

Parameters:

none

Return Parameters:

none

Notes:

5.3.22 dwt_setrxtimeout

```
void dwt_setrxtimeout (uint32_t time);
```

The [dwt_setrxtimeout\(\)](#) function sets the receiver to timeout (and disable) when no frame is received within the specified time. This function should be called before the [dwt_rxenable\(\)](#) function is called to turn on the receiver. The time parameter used here is in 1.0256 us (*UWB microseconds*, i.e. 512/499.2 MHz) units. The maximum RX timeout is ~ 1.0754s.

Parameters:

type	name	description
uint32_t	time	Timeout time in microseconds (1.0256 us). If this is 0, the timeout will be disabled. The max value is 0xFFFFF.

Return Parameters:

none

Notes:

If RX timeout is being employed then this function should be called before [dwt_rxenable\(\)](#) to configure the frame wait timeout time, and enable the frame wait timeout.

5.3.23 dwt_setrxaftertxdelay

```
void dwt_setrxaftertxdelay(uint32_t rxDelayTime);
```

This function sets the delay in turning the receiver on after a frame transmission has completed. The delay, [rxDelayTime](#), is in *UWB microseconds* (1 *UWB microsecond* is 512/499.2 microseconds). It is a 20-bit wide field. This should be set before start of frame transmission after which a response is expected, i.e. before invoking the [dwt_starttx\(\)](#) function (above) to initiate the transmission (in DWT_RESPONSE_EXPECTED mode). E.g. transmission of a frame with an ACK request bit set.

Parameters:

type	name	description
uint32_t	rxDelayTime	The turnaround time, in UWB microseconds, between the TX completion and the RX enable.

Return Parameters:

none

Notes:

This function is used to set the delay time before automatic receiver enable after a frame transmission. The smallest value that can be set is 0. If 0 is set the IC will turn the receiver on as soon

as possible, which approximately takes 6.2 μ s. So if setting a value smaller than 7 μ s it will still take 6.2 μ s to switch to receive mode.

5.3.24 dwt_setpreambledetecttimeout

```
void dwt_setpreambledetecttimeout (uint16_t time);
```

This [dwt_setpreambledetecttimeout\(\)](#) API function sets the receiver to timeout (and disable) when no preamble is received within the specified time. This function should be called before the [dwt_rxenable\(\)](#) function is called to turn on the receiver. The time parameter units are PACs (as per the [rxPAC](#) parameter in the [dwt_config_t](#) structure parameter to the [dwt_configure\(\)](#) API function call).

Parameters:

type	name	description
uint16_t	time	<p>This is the preamble detection timeout duration. If preamble is not detected within this time, counted from the time the receiver is enabled, the receiver will be turned off.</p> <p>The time here is specified in multiples of PAC size, (as per the rxPAC parameter in the dwt_config_t structure parameter to the dwt_configure() API function call). The IC automatically adds 1 to the configured value. A value of 0 disables the timer and timeout.</p>

Return Parameters:

none

Notes:

If preamble detection timeout is being employed, then this function should be called before [dwt_rxenable\(\)](#) is called.

5.3.25 dwt_readrxdata

```
void dwt_readrxdata(uint8_t *buffer, uint16_t len, uint16_t bufferOffset);
```

This function reads a number, [len](#), bytes from the IC receive data buffer, beginning at the specified offset, [bufferOffset](#), into the given buffer, [buffer](#).

Parameters:

type	name	description
uint8_t*	buffer	The pointer to the buffer into which the data will be read.
uint16_t	len	The length of data to be read (in bytes).
uint16_t	bufferOffset	The offset at which to start to read the data.

Return Parameters:

none

Notes:

This function should be called on the reception of a good frame to read the received frame data. The offset might be used to skip parts of the frame that the application is not interested in or has read previously.

5.3.26 dwt_read_rx_scratch_data

```
void dwt_read_rx_scratch_data(uint8_t *buffer, uint16_t length, uint16_t rxBufferOffset);
```

This is used to read the data from the RX scratch buffer, from an offset location given by offset parameter.

Parameters:

type	name	description
uint8_t*	buffer	The pointer to the buffer into which the data will be read.
uint16_t	length	The length of data to be read (in bytes).
uint16_t	rxBufferOffset	The offset at which to start to read the data.

Return Parameters:

none

Notes:

This function should be called on the reception of a good frame to read the received frame data. The offset might be used to skip parts of the frame that the application is not interested in or has read previously.

5.3.27 dwt_readpgdelay

```
uint8_t dwt_readpgdelay(void);
```

This is used to read the pulse generator delay value of the TX signal.

Parameters:

none

Return Parameters:

type	description
uint8_t	Pulse generator delay read from TX_CTRL_HI register.

Notes:

5.3.28 dwt_readtdoa

```
void dwt_readtdoa(uint8_t * tdoa);
```

This function is used to read the TDOA (Time Difference On Arrival). The TDOA value that is read from the register is 41-bits in length. However, 6 bytes (or 48 bits) are read from the register. The remaining 7 bits at the 'top' of the 6 bytes that are not part of the TDOA value should be set to zero and should not interfere with rest of the 41-bit value. However, there is no harm in masking the returned value.

Parameters:

type	name	description
uint8_t*	tdoa	Time difference on arrival - buffer of 6 bytes that will be filled with TDOA value by calling this function.

Return Parameters:

none

Notes:

5.3.29 dwt_repeated_cw

```
void dwt_repeated_cw(int pulsegen_channel, int pulsegen_coefficient);
```

This function will enable a repeated continuous waveform on the selected device given a pulse generator channel and pulse generator coefficient.

Parameters:

type	name	description
int	pulsegen_channel	Channel to use for pulse generation.
int	pulsegen_coefficient	Coefficient to use for pulse generation.

Return Parameters:

none

Notes:

5.3.30 dwt_repeated_frames

```
void dwt_repeated_frames(uint32_t framerepetitionrate);
```

This function enables repeated frames to be generated given a frame repetition rate.

Parameters:

type	name	description
uint32_t	framerepetitionrate	Value specifying the rate at which frames will be repeated. If the value is less than the frame duration, the frames are sent back-to-back.

Return Parameters:

none

Notes:

5.4 Sleep/Wakeup APIs

5.4.1 dwt_calibratesleepcnt

```
uint16_t dwt_calibratesleepcnt (void);
```

The [*dwt_calibratesleepcnt\(\)*](#) function calibrates the low-power oscillator. It returns the number of XTAL cycles per one low-power oscillator cycle.

Parameters:

none

Return Parameters:

type	description
uint16_t	This is number of XTAL cycles per one low-power oscillator cycle.

Notes:

The IC's internal L-C oscillator has an oscillating frequency which is between approximately 15,000 and 34,000 Hz depending on process variations within the IC and on temperature and voltage. To do more precise setting of sleep times its calibration is necessary. See also example code given under the [*dwt_configuresleepcnt\(\)*](#) function. This function needs to be run before [*dwt_configuresleepcnt\(\)*](#) in order to ascertain the counter units required to calculate the sleep time.

5.4.2 dwt_configuresleepcnt

```
void dwt_configuresleepcnt (uint16_t sleepcnt);
```

The [*dwt_configuresleepcnt\(\)*](#) function configures the sleep counter to a new value. This function needs to be run before [*dwt_configuresleep\(\)*](#).

Parameters:

type	name	description
uint16_t	sleepcnt	This is the sleep count value to set. The high 16-bits of 28-bit counter. See note below for details of units and code example for configuration detail.

Return Parameters:

none

Notes:

The units of the [sleepcnt](#) parameter depend on the oscillating frequency of the IC's internal L-C oscillator, which is between approximately 15,000 and 34,000 Hz depending on process variations within the IC and on temperature and voltage. This frequency can be measured using the [dwt_calibratesleepcnt\(\)](#) function so that sleep times can be more accurately set.

The [sleepcnt](#) is actually setting the upper 16 bits of a 28-bit counter, i.e. the low order bit is equal to 4096 counts. So, for example, if the L-C oscillator frequency is 15000 Hz then programming the [sleepcnt](#) with a value of 24 would yield a sleep time of $24 \times 4096 \div 15000$, which is approximately 6.55 seconds.

Example code:

This example shows how to calibrate the low-power oscillator and set the sleep time to 10 seconds.

```

Double t;
uint32_t sleep_time = 0;
uint16_t lp_osc_cal = 0;
uint16_t sleepTime16;

// Measure low power oscillator frequency

lp_osc_cal = dwt_calibratesleepcnt();

// calibrate low power oscillator
// the lp_osc_cal value is number of XTAL cycles in one cycle of LP OSC
// to convert into seconds (38.4 MHz => 1/38.4 MHz ns)
// so to get a sleep time of 10s we need a value of:
// 10 / period and then >> 12 as the register holds upper 16-bits of 28-bit
// counter

t = ((double) 10.0 / ((double) lp_osc_cal/38.4e6));
sleep_time = (int) t;
sleepTime16 = sleep_time >> 12;

dwt_configuresleepcnt(sleepTime16);           //configure sleep time

```

5.4.3 dwt_configuresleep

```
void dwt_configuresleep(uint16_t mode, uint8_t wake);
```

The [dwt_configuresleep\(\)](#) function may be called to configure the activity of DEEPSLEEP or SLEEP modes. Note TX and RX configurations are maintained in DEEPSLEEP and SLEEP modes so that upon "waking up" there is no need to reconfigure the devices before initiating a TX or RX, although as the TX data buffer is not maintained the data for transmission will need to be written before initiating transmission.

Parameters:

Type	name	description
uint16_t	mode	A bit mask which configures which configures the SLEEP parameters, see Table 15.
uint8_t	wake	A bit mask that configures the wakeup event. As defined in Table 16

Return Parameters:

none

Notes:

This function is called to configure the sleep and on wake parameters.

Table 15: Bitmask values for `dwt_configuresleep()` *mode* bit mask

Event	Bit mask	Description
DWT_PGFCAL	0x0800	On wake-up, run the PGF calibration.
DWT_GOTORX	0x0200	On wake-up, go to the RX state via IDLE.
DWT_GOTOIDLE	0x0100	On wake-up, go to the IDLE state with PLL calibration.
DWT_SEL_GEAR	0x0040 0x0080	On wake-up, select which gear table to load.
DWT_LOADGEAR	0x0020	On wake-up, load the gear table specified by DWT_SEL_GEAR.
DWT_LOADLDO	0x0010	On wake-up, load the LDO tune codes from OTP.
DWT_LOADDGC	0x0008	On wake-up, populate the DGC table from settings in OTP.
DWT_LOADBIAS	0x0004	On wake-up, load the bias settings from OTP.
DWT_RUNSAR	0x0002	On Wake-up run the (temperature and voltage) ADC. Setting this bit will cause the automatic initiation of temperature and input battery voltage measurements when the IC wakes from DEEPSLEEP or SLEEP states. The sampled temperature value may be accessed using the dwt_readwakeuptemp() function and, the sampled battery voltage value may be accessed using the dwt_readwakeupybat() function
DWT_CONFIG	0x0001	Restore saved configurations.

Table 16: Bitmask values for `dwt_configuresleep()` *wake* bit mask

Event	Bit mask	Description
DWT_SLP_CNT_RPT	0x40	sleep counter loop after expiration.
DWT_PRESERVE_SLP	0x20	The sleep enable (bit 0) will be restored after wakeup.
DWT_WAKE_WK	0x10	Wakeup on chip select, SPICSn, line.

Event	Bit mask	Description
DWT_WAKE_CS	0x8	Wakeup on chip select, SPICSn, line.
DWT_BR_DET	0x4	Enable brownout detector during SLEEP/DEEPSLEEP
DWT_SLEEP	0x2	Device will use DEEPSLEEP mode unless this is set, then it will use SLEEP mode.
DWT_SLP_EN	0x1	This is the sleep enable configuration bit. This needs to be set to enable the SLEEP/DEEPSLEEP functionality.

The DEEPSLEEP state is the lowest power state except for the OFF state. In DEEPSLEEP all internal clocks and LDO are off and the IC consumes approximately 100 nA. To wake the IC from DEEPSLEEP an external pin needs to be activated for the “power-up duration” approximately 300 to 500 μ s. This can be either be the SPICSn line pulled low or the WAKEUP line driven high. The duration quoted here is dependent on the frequency of the low power oscillator (enabled as the IC comes out of DEEPSLEEP) which will vary between individual IC and will also vary with changes of battery voltage and different temperatures. To ensure the IC reliably wakes up it is recommended to either apply the wakeup signal until the 500 μ s has passed, or to use the SPIRDY event status bit (in Register file: 0x0F – System Event Status Register) to drive the IRQ interrupt output line high to confirm the wake-up. Once the IC has detected a “wake up” it progresses into the WAKEUP state. While in DEEPSLEEP power should not be applied to GPIO, SPICLK or SPIMISO pins as this will cause an increase in leakage current.

There are four mechanisms to awaken the IC:

- By driving the WAKEUP pin (pin 23) high for a period > 500 μ s (as per the Data Sheet [1])
- Driving SPICSn low for a period > 500 μ s. This can also be achieved by an SPI read (of register 0, offset 0) of sufficient length
- If the IC is sleeping using its own internal sleep counter it will be awoken when the timer expires. This is configured by setting the *wake* parameter to 0x10 (+ 0x1 – to enable sleep).
- By resetting the device, setting RSTn pin to low.

Example code:

This example shows how to configure the device to enter DEEPSLEEP mode after some event e.g. frame transmission. The mode parameter into the *dwt_configuresleep()* function has value 0x01 which configures DW3000 to load IC configurations. The wake parameter value, 0x29, which enables the sleeping with SPICSn as the wakeup signal, and also sets the preserve sleep bit setting.

```
dwt_configuresleep(0x01, 0x29); //configure sleep and wake parameters

// then ... later... after some event we can instruct the IC to go into
// DEEPSLEEP mode

dwt_entersleep(); //go to sleep

/// then ... later ... when we want to wake up the device

dwt_spicswakeup(buffer, len);

// buffer is declared locally and needs to be of length (len) which must be
// sufficiently long keep the SPI CSn pin low for at least 500us this
// depends on SPI speed - see also dwt_spicswakeup() function
```

5.4.4 dwt_entersleep

```
void dwt_entersleep(int idle_rc);
```

This function is called to put the device into DEEPSLEEP or SLEEP mode.

NOTE: [dwt_configuresleep\(\)](#) needs to be called before calling this function to configure the sleep and on wake parameters.

(Before entering DEEPSLEEP, the device should be programmed for TX or RX, then upon “waking up” the TX/RX settings will be preserved and the device can immediately perform the desired action TX/RX see [dwt_configuresleep\(\)](#)).

Parameters:

Type	name	description
int	idle_rc	If this is set to DWT_DW_IDLE_RC, the auto INIT2IDLE bit will be cleared prior to going to sleep. Thus, after wake-up, device will stay in IDLE_RC state.

Return Parameters:

none

Notes:

This function is called to enable (put the device into) DEEPSLEEP mode. The [dwt_configuresleep\(\)](#) should be called first to configure the sleep/wake parameters. (See code example in the [dwt_configuresleep\(\)](#) function).

5.4.5 dwt_entersleepaftertx

```
void dwt_entersleepaftertx (int enable);
```

The [dwt_entersleepaftertx\(\)](#) function configures the “enter sleep after transmission completes” bit. If this is set, the device will automatically go to DEEPSLEEP/SLEEP mode after a TX event.

Parameters:

type	name	description
int	enable	If set the “enter DEEPSLEEP/SLEEP after TX” bit will be set, else it will be cleared.

Return Parameters:

none

Notes:

When this mode of operation is enabled the IC will automatically transition into SLEEP or DEEPSLEEP mode (depending on the sleep mode configuration set in [dwt_configuresleep\(\)](#)) after transmission of a frame has completed so long as there are no unmasked interrupts pending. See [dwt_setinterrupt\(\)](#) for details of controlling the masking of interrupts.

To be effective [`dwt_entersleepaftertx\(\)`](#) function should be called before [`dw_starttx\(\)`](#) function and then upon TX event completion the device will enter sleep mode.

Example code:

This example shows how to configure the device to enter DEEP_SLEEP mode after frame transmission.

```
dwt_configuresleep(0x01, 0x25);           //configure the on-wake parameters
                                           //(upload the IC config settings)

dwt_entersleepaftertx(1);                 //configure the auto go to sleep
                                           //after TX

dwt_setinterrupt(DWT_INT_TFRS, 0);        //disable TX interrupt

// won't be able to enter sleep if any other unmasked events are pending

dwt_writetxdata(frameLength,DataBufferPtr,0); // write the frame data at
                                           //offset 0

dwt_writetxfctrl(frameLength,0,0)         // set the frame control register

dwt_starttx(DWT_START_TX_IMMEDIATE);      // send the frame immediately

// when TX completes the IC will go to sleep....then....later...when we
// want to wake up the device

dwt_spicswakeup(buffer, len);

// buffer is declared locally and needs to be of length (len) which must be
// sufficiently long keep the SPI CSn pin low for at least 500us this
// depends on SPI speed - see also dwt\_spicswakeup\(\) function
```

5.4.6 dwt_spicswakeup

```
int dwt_spicswakeup (uint8_t *buff, uint16_t length);
```

The [`dwt_spicswakeup\(\)`](#) function uses an SPI read to wake up the IC from SLEEP or DEEPSLEEP.

Parameters:

type	name	description
uint8_t*	buff	This is the pointer to a buffer where the data from SPI read will be read into.
uint16_t	length	This is the length of the input buffer.

Return Parameters:

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

When the IC is in DEEPSLEEP or SLEEP mode, this function can be used to wake it up, assuming SPICSn has been configured as a wakeup signal in the [dwt_configuresleep\(\)](#) call. This is done using an SPI read. The duration of the SPI read, keeping SPICSn low, has to be long enough to provide the low for a period > 500 μ s.

See example code below.

Example code:

This example shows how to configure the device to enter DEEPSLEEP mode after some event e.g. frame transmission.

```
dwt_configuresleep(0x01, 0x25); //configure sleep and wake parameters

// then ... later....after some event we can instruct the IC to go into
// DEEPSLEEP mode

dwt_entersleep();                //go to sleep

// then ... later ... when we want to wake up the device

dwt_spicswakeup(buffer, len);

// buffer is declared locally and needs to be of length (len) which must be
// sufficient to keep the SPI CSn pin low for at least 500us This depends
// on SPI speed
```

5.4.7 dwt_readwakeuptemp

```
uint8_t dwt_readwakeuptemp(void);
```

This function reads the IC temperature sensor value that was sampled during IC wake-up.

Parameters:

none

Return Parameters:

type	description
uint8_t	The 8-bits are temperature value sampled at wake-up event.

Notes:

This function may be used to read the temperature sensor value that was sampled by the IC on wake up, assuming the DWT_TANDV bit in the mode parameter was set in a call to [dwt_configuresleep\(\)](#) before entering sleep mode. If the wakeup sampling of the temperature sensor was not enabled then the value returned by [dwt_readwakeuptemp\(\)](#) will not be valid.

5.4.8 dwt_readwakeupvbat

```
uint8_t dwt_readwakeupvbat(void);
```

This function reads the battery voltage sensor value that was sampled during IC wake-up.

Parameters:

none

Return Parameters:

type	description
uint8_t	The 8-bits are voltage value sampled at wake-up event.

Notes:

This function may be used to read the battery voltage sensor value that was sampled by the IC on wake up, assuming the DWT_TANDV bit in the mode parameter was set in the call to [dwt_configuresleep\(\)](#) before entering sleep mode. If the wakeup sampling of the battery voltage sensor was not enabled then the value returned by [dwt_readwakeuptbat\(\)](#) will not be valid.

5.4.9 dwt_wakeup_ic

```
void dwt_wakeup_ic(void);
```

This function will wake up the device by toggling the correct IO pin. DW3000 SPI_CS or WAKEUP pins can be used for this.

Parameters:

none

Return Parameters:

none

Notes:

This function is platform dependent. This is due to the fact that each platform may configure IO pins differently. Please view the source code of this function to see how it can be ported to other platforms.

5.5 ISR and callback APIs**5.5.1 dwt_setcallbacks**

```
void dwt_setcallbacks( dwt_cb_t cbTxDone, dwt_cb_t cbRxOk, dwt_cb_t cbRxTo,
                      dwt_cb_t cbRxErr, dwt_cb_t cbSPIErr, dwt_cb_t cbSPIRdy);
```

This function is used to configure the TX/RX callback function pointers, and SPI CRC error callback function pointer. These callback functions will be called when TX, RX or SPI error events happen and the [dwt_isr\(\)](#) is called to handle them (See [dwt_isr\(\)](#) description below for more details about the events and associated callback functions).

Parameters:

type	name	Description
dwt_cb_t	cbTxDone	Function pointer for the cbTxDone function. See type description below.
dwt_cb_t	cbRxOk	Function pointer for the cbRxOk function. See type description below.
dwt_cb_t	cbRxTo	Function pointer for the cbRxTo function. See type description below.
dwt_cb_t	cbRxErr	Function pointer for the cbRxErr function. See type description below.
dwt_cb_t	cbSPIErr	Function pointer for the cbSPIErr function. See type description below.
dwt_cb_t	cbSPIRdy	Function pointer for the cbSPIRdy function. See type description below.

```
// Call-back type for all events
typedef void (*dwt_cb_t)(const dwt_cb_data_t *);

// TX/RX call-back data
typedef struct
{
    uint32_t status;          //initial value of register as ISR is entered
    uint16_t datalength;      //length of frame
    uint8_t  fctrl[2];        //frame control bytes
    uint8_t  rx_flags;        //RX frame flags
}dwt_cb_data_t;
```

Return Parameters:

none

Notes:

This function is used to set up the TX and RX events call-back functions.

Fields	Description of fields within the <i>dwt_cb_data_t</i> structure
<i>status</i>	The <i>status</i> parameter holds the initial value of the status (0xF) register as read on entry into the ISR.
<i>datalength</i>	The <i>datalength</i> parameter specifies the length of the received frame.
<i>fctrl[2]</i>	The <i>fctrl</i> is the two byte array holding the two frame control bytes.
<i>rx_flags</i>	<p>The <i>rx_flags</i> parameter is a bit field value valid only for received frames. It is interpreted as follows:</p> <ul style="list-style-type: none"> - Bit 0: 1 if the ranging bit was set for this frame, 0 otherwise. - Bit 1: 1 if no data STS mode (no RX data but timestamps are valid) - Bit 2: CIA done (the RX timestamps and diagnostics are valid) - Bit 3: CIA error (the RX timestamps are not valid) - Bit 4-7: Reserved.

For more detailed information on interrupt events and especially for details on which status events trigger each one of the different callback functions, see [dwt_isr\(\)](#) function description below.

5.5.2 dwt_setinterrupt

```
void dwt_setinterrupt(uint32_t bitmask_lo, uint32_t bitmask_hi, dwt_INT_options_e INT_options);
```

This function sets the events which will generate an interrupt. The bit mask parameters may be used to enable or disable single events or multiple events at the same time. Table 17 shows the main events that are typically configured as interrupts:

Parameters:

type	name	description
uint32_t	bitmask_lo	This specifies the events being acted on by this API. See Table 17 for the relevant events.
uint32_t	bitmask_hi	This specifies the additional events being acted on by this API. For more information, please see details of the SYS_ENABLE_HI register in the DW3000 User Manual [2].
dwt_INT_options_e	INT_options	<p>The operation parameter selects the operation being applied to the selected event bits. This can be:</p> <p>DWT_DISABLE_INT (0) = clear only selected bits (other bits settings unchanged).</p> <p>DWT_ENABLE_INT (1) = set only selected bits (other bits settings unchanged).</p> <p>DWT_ENABLE_INT_ONLY (2) = set only selected bits, force other bits to clear.</p>

Return Parameters:

none

Notes:

This function is called to enable/disable events for which to generate interrupts.

For the transmitter, it is generally sufficient to enable the SY_STAT_TFRS event which will trigger when a frame has been sent. For the receiver, it is generally sufficient to enable the good frame reception event (DWT_INT_RFCG) and also any error events which will disable the receiver.

Table 17: bitmask_lo values for control of common event interrupts

Event	Bit mask	Description
DWT_INT_SCRC	0x00000004	SPI write CRC error event. This is set when IC detects a mismatch between the 8-bit CRC set by the host at the end of the host SPI write transaction and the CRC calculated by the IC. When SPI CRC mode is enabled this may be used to detect SPI errors. The event bit is always set when SPI CRC mode is disabled, therefore the mask should not be set to avoid this causing interrupts.
DWT_INT_TFRS	0x00000080	Transmit Frame Sent: This is set when the transmitter has completed the sending of a frame.
DWT_INT_RPHE	0x00001000	Receiver PHY Header Error: Reception completed, Frame Error
DWT_INT_RFCG	0x00004000	Receiver FCS Good: The CRC check has matched the transmitted CRC, frame should be good
DWT_INT_RFCE	0x00008000	Receiver FCS Error: The CRC check has not matched the transmitted CRC, frame has some error
DWT_INT_RFSL	0x00010000	Receiver Frame Sync Loss: The RX lost signal before frame was received, indicates excessive Reed Solomon decoder errors
DWT_INT_RFTO	0x00020000	Receiver Frame Wait Timeout: The RX_FWTO time period expired without a Frame RX.
DWT_INT_SFDT	0x04000000	SFD Timeout
DWT_INT_RXPTO	0x00200000	Preamble detection timeout
DWT_INT_LCSSERR	0x00400000	LCSS set up error. The STS timestamp should not be trusted.
DWT_INT_ARFE	0x20000000	ARFE – frame rejection status

5.5.3 dwt_checkirq

```
uint8_t dwt_checkirq(void);
```

This API function checks the interrupt line status.

Parameters:

none

Return Parameters:

type	Description
uint8_t	1 if the IC interrupt line is active (IRQS bit in STATUS register is set), 0 otherwise.

Notes:

This function is typically intended to be used in a PC based system using (Cheetah or ARM) USB to SPI converter, where there can be no interrupts. In this case we can operate in a polled mode of operation by checking this function periodically and calling [dwt_isr\(\)](#) if it returns 1.

5.5.4 dwt_isr

```
void dwt_isr(void);
```

This function processes device events, (e.g. frame reception, transmission). It is intended that this function be called as a result of an interrupt from the IC – the mechanism by which this is achieved is target specific. Where interrupts are not supported this function can be called from a simple runtime loop to poll the status register and take the appropriate action, but this approach is not as efficient and may result in reduced performance depending on system characteristics.

The [dwt_isr\(\)](#) function makes use of call-back functions in the application to indicate that received data is available to the upper layers (application) or to indicate when frame transmission has completed. The [dwt_setcallbacks\(\)](#) API function is used to configure the call back functions.

The [dwt_isr\(\)](#) function reads the status register and recognises the following events:

Table 18: List of events handled by the [dwt_isr\(\)](#) function and signalled in call-backs

Event	Corresponding status register event flags	Comments
Reception of a good frame (cbRxOk callback)	RXFCG	This means that a frame with a good CRC has been received and that the RX data and the frame receive time stamp can be read. Frame length and frame control information are reported through “datalength” and “fctrl” fields of the <i>dwt_cb_data_t</i> structure. The value of the Ranging bit (from the PHY header), is reported through RNG bit in the rx_flags field of the <i>dwt_cb_data_t</i> structure. When automatic acknowledgement is enabled (via the dwt_enableautoack() API function), if a frame is received with the ACK request bit set then the AAT bit will be set in the “status” field of the <i>dwt_cb_data_t</i> structure, indicating that an ACK is being sent (or has been sent).
Reception of good STS Mode 3 (no data) packet (cbRxOk callback)	RXFR	Since the STS mode 3 (no data) packet contains no PHY payload, the way in which a ‘good’ packet is checked for is different. The required event for this callback is a simplified version of the callback described above (for a good frame). There is no CRC and no RX data to be checked in this case. Nor is the any frame length or control to cater for. All that is required is the RXFR bit set and STS mode 3 is configured.
Reception timeout (cbRxTo callback)	RXRFTO/RXPTO	These events indicate that a timeout occurred while waiting for an incoming frame. If needed, the “status” field of the <i>dwt_cb_data_t</i> structure can be examined to distinguish between these events.
Reception error (cbRxErr callback)	RXRPHE/RXSFDTO/ RXRFSL/RXRFCF/	This means that an error event occurred while receiving a frame.

Event	Corresponding status register event flags	Comments
	LDEERR/AFFREJ/ LCSSERR	If needed, the “status” field of <i>dwt_cb_data_t</i> structure can be examined to determine which event caused the interrupt.
Transmission of a frame completed (cbTxDone callback)	TXFRS	This means that the transmission of a frame is complete and that the transmit time stamp can be read.
SPI write CRC error detected (cbSPIErr callback)	SPICRCERR	This means that the CRC byte written by the host as the last byte of SPI write transaction did not match the CRC generated by the IC on the header and data bytes. This will only be generated when IC is using SPI CRC mode.
Device powered on or wake-up (cbSPIRdy callback)	SPIRDY/ RCINIT	This callback is used to check if the device has powered up or has woken up from a sleep state. It checks for the SPI to be ready and that the device has gone from wakeup to the RXINIT state.

When an event is recognised and processed the status register bit is cleared to clear the event interrupt. Figure 6 below shows the *dwt_isr()* function flow diagram.

Parameters :

none

Return Parameters :

none

Notes :

The *dwt_isr()* function should be called from the microprocessor’s interrupt handler that is used to process the IC interrupt.

It is recommended to read the User Manual [2], especially chapters 3, 4, and 5 to become familiar with IC events and their operation.

In addition, if the microprocessor is not fast enough and two events are set in the status register, the order in which they are processed is as shown in Figure 6 below. This may not be the order in which they were triggered.

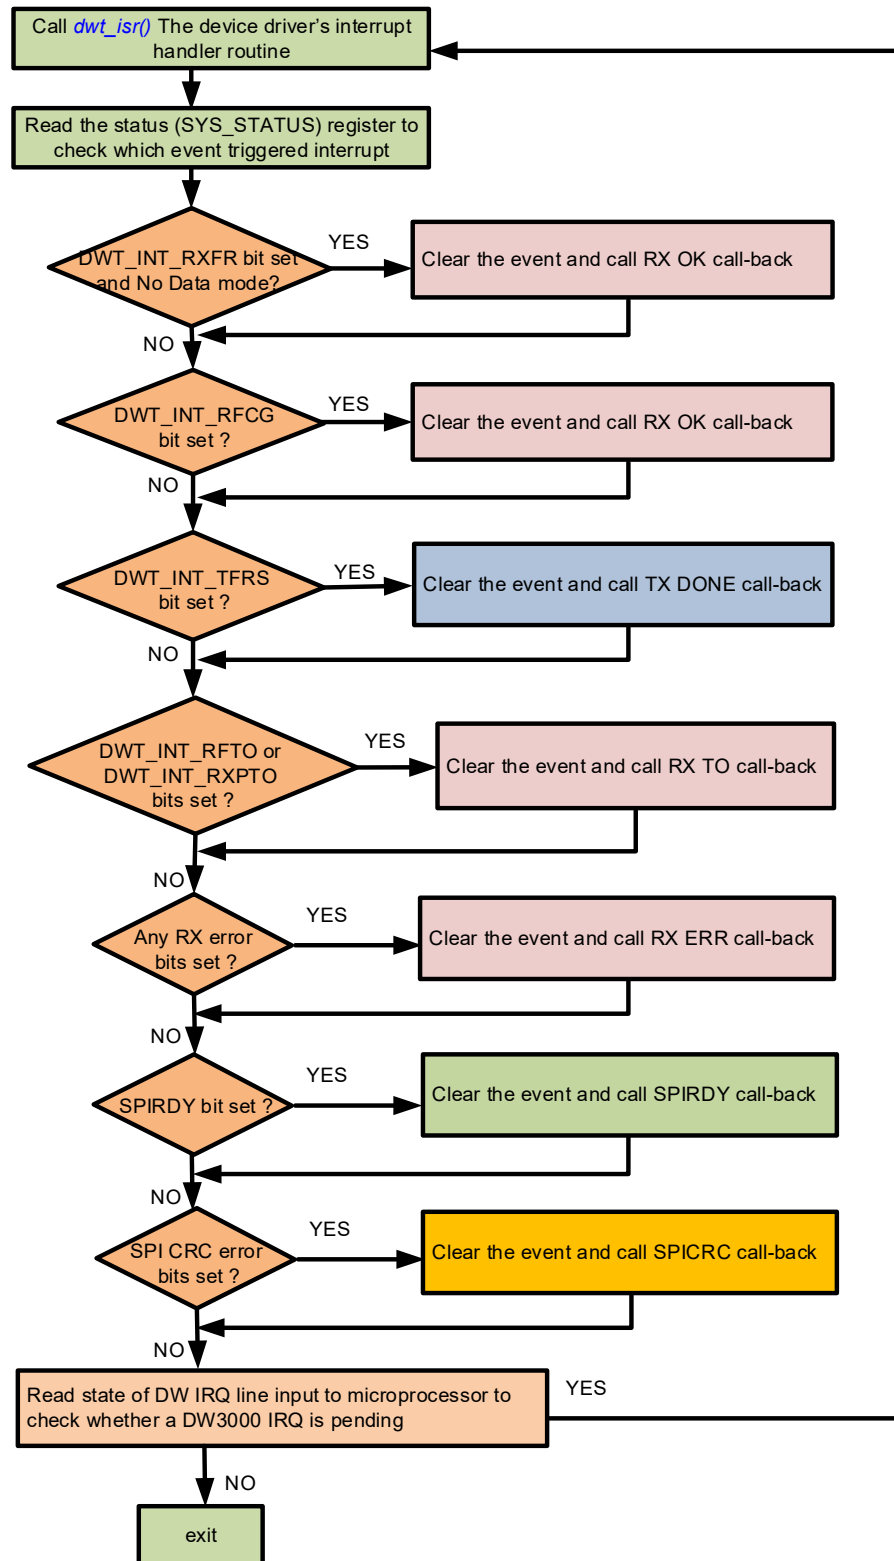

Figure 6: Interrupt handling

5.6 MAC configuration APIs

5.6.1 dwt_setpanid

```
void dwt_setpanid(uint16_t panID);
```

This function sets the PAN ID value. These are typically assigned by the PAN coordinator when a node joins a network. This value is only used by the IC for frame filtering. See the [dwt_\(\)](#) function.

Parameters:

type	name	description
uint16_t	panID	This is the PAN ID.

Return Parameters:

none

Notes:

This function can be called to set device's PANID for frame filtering use, it does not need to be set if frame filtering is not being used. Insertion of PAN ID in the TX frames is the responsibility of the upper layers calling the [dwt_writetxdata\(\)](#) function.

5.6.2 dwt_setaddress16

```
void dwt_setaddress16(uint16_t shortAddress);
```

This function sets the 16-bit short address values. These are typically assigned by the PAN coordinator when a node joins a network. This value is only used by the IC for frame filtering. See the [dwt_\(\)](#) function.

Parameters:

type	name	description
uint16_t	shortAddress	This is the 16-bit address to set.

Return Parameters:

none

Notes:

This function is called to set device's short (16-bit) address, it does not need to be set if frame filtering is not being used. Insertion of short (16-bit) address, in the TX frames is the responsibility of the upper layers calling the [dwt_writetxdata\(\)](#) function.

5.6.3 dwt_seteui

```
void dwt_seteui (uint8_t* eui);
```

The [dwt_seteui\(\)](#) function sets the 64-bit address.

Parameters:

type	name	description
uint8_t*	eui	This is a pointer to the 64-bit address to set, arranged as 8 unsigned bytes. The low order byte comes first.

Return Parameters:

none

Notes:

This function may be called to set a long (64-bit) address used for address filtering. If address filtering is not being used, then this register does not need to be set.

It is possible for a 64-bit address to be programmed into the IC's one-time programmable memory (OTP memory) during customers' manufacturing processes and automatically loaded into this register on power-on reset or wake-up from sleep. [dwt_seteui\(\)](#) may be used subsequently to change the value automatically loaded.

5.6.4 dwt_geteui

```
void dwt_geteui (uint8_t* eui64);
```

The [dwt_geteui\(\)](#) function gets the programmed 64-bit EUI value.

Parameters:

type	name	description
uint8_t*	eui64	This is a pointer to the 64-bit address to read, arranged as 8 unsigned bytes. The low order byte comes first.

Return Parameters:

none

Notes:

This function may be called to get the the EUI value. The value will be 0xFFFFFFFF00000000 if it has not been programmed into OTP memory or has not been set by a call to [dwt_seteui\(\)](#) function.

It is possible for a 64-bit address to be programmed into the IC's one-time programmable memory (OTP memory) during customers' manufacturing processes and automatically loaded into this register on power-on reset or wake-up from sleep. [dwt_seteui\(\)](#) may be used subsequently to change the value automatically loaded.

5.6.5 dwt_configureframefilter

```
void dwt_configureframefilter(uint16_t enabletype, uint16_t filtermode) ;
```

This [dwt_\(\)](#) function enables frame filtering according to the [mask](#) parameter.

Parameters:

type	name	description
------	------	-------------

uint16_t	enabletype	This enables 802.15.4 frame filter (DWT_FF_ENABLE_802_15_4) or disables the frame filter (DWT_FF_DISABLE)
uint16_t	filterode	This enables a particular frame filter options, see Table 19.

Return Parameters:

none

Notes:

This function is used to enable frame filtering, the device address and pan ID should be configured beforehand.

Table 19: Bitmask values for frame filtering enabling/disabling

Definition	Value	Description
DWT_FF_BEACON_EN	0x001	Beacon frames allowed
DWT_FF_DATA_EN	0x002	Data frames allowed
DWT_FF_ACK_EN	0x004	ACK frames allowed
DWT_FF_MAC_EN	0x008	MAC command frames allowed
DWT_FF_RSVD_EN	0x010	Reserved frame types allowed
DWT_FF_MULTI_EN	0x020	Multipurpose frame types allowed
DWT_FF_FRAG_EN	0x040	Fragmented frame types allowed
DWT_FF_EXTEND_EN	0x080	Extended frame types allowed
DWT_FF_COORD_EN	0x100	behave as coordinator (can receive frames with no destination address (PAN ID has to match))
DWT_FF_IMPBRCAST_EN	0200	MAC implicit Broadcast allowed.

5.6.6 dwt_configure_le_address

```
void dwt_configure_le_address(uint16_t addr, int leIndex);
```

This function is used to write a 16 bit address to a desired Low-Energy device (LE) address. For frame pending to function when the correct bits are set in the frame filtering configuration via the [dwt_configureframefilter\(\)](#). See [dwt_configureframefilter\(\)](#) for more details.

Parameters:

type	name	description
uint16_t	addr	The uint16_t address value to be written to the selected LE register
int	leIndex	The Low-Energy device (LE) address to write to. There are four options for this index: 0, 1, 2 & 3. The index the LE_PEND_01

		register with offset 0 (LE_ADDR0), LE_PEND_01 register with offset 16 (LE_ADDR1), LE_PEND_23 register with offset 0 (LE_ADDR2) and LE_PEND_23 with offset 16 (LE_ADDR3) respectively.
--	--	---

Return Parameters:

none

5.6.7 dwt_enableautoack

```
void dwt_enableautoack(uint8_t responseDelayTime, int enable);
```

This function enables automatic ACK to be automatically sent when a frame with ACK request is received. The ACK frame is sent after a specified responseDelayTime (in preamble symbols, max is 255). It can also be enabled or disabled depending on how the *enable* parameter is set.

Parameters:

type	name	description
uint8_t	responseDelayTime	The delay between the ACK request reception and ACK transmission.
int	enable	This argument enables the Auto-ACK feature with '1' and disables it with '0'.

Return Parameters:

none

Notes:

This *dwt_enableautoack()* function is used to enable the automatic ACK response. It is recommended that the *responseDelayTime* is set as low as possible consistent with the ability of unit requesting the ACK to turn around and be ready to receive the response. If the host system is using the DWT_RESPONSE_EXPECTED mode (with *rxDelayTime* in *dwt_setrxaftertxdelay()* function set to 0) in the *dwt_starttx()* function then the *responseDelayTime* can be set to 3 symbols (3 μ s) without loss of preamble symbols in the receiver awaiting the ACK.

5.6.8 dwt_readacccdata

```
void dwt_readacccdata(uint8_t *buffer, uint16_t len, uint16_t sampleOffset);
```

This API function reads data from the IC's accumulator memory. This data represents the channel impulse response (CIR) of the RF channel. Reading this data is not required in normal operation but it may be useful for diagnostic purposes. The accumulator contains complex values, each comprised of an 18-bit real integer and an 18-bit imaginary integer, for each tap of the accumulator. Each complex

value represents a 1 ns sample interval (or more precisely half a period of the 499.2 MHz fundamental frequency).

When STS mode is enabled there are two separate accumulations and two CIRs: one during the Ipatov sequence and one during the STS, both may be read using this [dwt_readaccddata\(\)](#) API function. The Ipatov sequence begins at offset 0 and has a span of one symbol time (This is 992 samples for the nominal 16 MHz mean PRF, or, 1016 samples for the nominal 64 MHz mean PRF). The STS begins at offset 1024 and has a span of half a symbol time (512 samples irrespective of PRF setting). If PDOA mode 3 is used, the STS CIR will be split into two. One half of STS symbols and corresponding CIR will be received through one antenna port and saved into CIR memory from 1024 to 1535, and the second half of STS symbols will be received through the other antenna port and saved into CIR memory from 1536 to 2047.

The [dwt_readaccddata\(\)](#) function reads, [len](#), bytes of accumulator buffer data, from a given offset, [sampleOffset](#), into the memory pointed to by the supplied [buffer](#) parameter. Each 18-bit complex sample has 3 bytes of real and 3 bytes of imaginary data (delivered by the IC as signed 24-bit numbers). The accumulator data starts from [buffer\[1\]](#). The first byte written to [buffer\[0\]](#) is always a dummy byte, and to allow for this the specified length should always be 1 bigger than the length required.

For example to read the first 2 complex samples of the CIR the function should be done as shown in the example below:

Example code:

```
uint8_t cir_buiffer[xx] ;

dwt_readaccddata(uint8_t *buffer, uint16_t len, uint16_t sampleOffset);
```

Note that the length is in bytes while the offset is in complex samples.

Both accumulators can be read together in this case length should be 1536*6 + 1 bytes.

Parameters:

type	name	description
uint8_t*	buffer	The pointer to the destination buffer into which the read accumulator data will be written.
uint16_t	len	The length of data to be read (in bytes). Since each complex value occupies six octets, the value used here should naturally be a multiple of six, plus 1 for the dummy byte as described above. Maximum length is 9217
uint16_t	bufferOffset	The offset at which to start to read the data. Offset 0 should be used when reading the full accumulator.

Return Parameters:

none

Notes:

`dwt_readaccddata()` may be called after frame reception to read the accumulator data for diagnostic purposes. The accumulator is not double buffered so this access must be done before the receiver is re-enabled otherwise the accumulator data may be overwritten during the reception of the next frame. The data returned in the buffer has the following format (for `bufferOffset` input of zero):

buffer index	Description of elements within buffer
0	Dummy Octet
1	Low 8 bits of real part of accumulator sample index 0
2	Mid 8 bits of real part of accumulator sample index 0
3	High 8 bits of real part of accumulator sample index 0
4	Low 8 bits of imaginary part of accumulator sample index 0
5	Mid 8 bits of imaginary part of accumulator sample index 0
6	High 8 bits of imaginary part of accumulator sample index 0
7	Low 8 bits of real part of accumulator sample index 1
8	Mid 8 bits of real part of accumulator sample index 1
9	High 8 bits of real part of accumulator sample index 1
10	Low 8 bits of imaginary part of accumulator sample index 1
:	:

In examining the CIR it is normal to compute the magnitude of the complex values.

5.6.9 dwt_configciadiag

```
void dwt_configciadiag (int enable_mask);
```

This function can be used to enable full or partial CIA diagnostic calculations in the IC during reception processing of frame. Note partial diagnostics are enabled by default in the IC.

Parameters:

Type	Name	description
int	enable_mask	Table 20 lists the allowed values.

Table 20: Values for `dwt_configciadiag()` *enable_mask* parameter

Event	Bit mask	Description
DW_CIA_DIAG_LOG_MIN	0x0	CIA to log reduced set of diagnostic registers
DW_CIA_DIAG_LOG_ALL	0x1	CIA to log the whole set of diagnostic registers
DW_CIA_DIAG_LOG_MIN	0x2	CIA to copy to swinging set a minimal set of diagnostic registers in Double Buffer mode
DW_CIA_DIAG_LOG_MID	0x4	CIA to copy to swinging set a medium set of diagnostic registers in Double Buffer mode.
DW_CIA_DIAG_LOG_MAX	0x8	CIA to copy to swinging set a maximum set of diagnostic registers in Double Buffer mode.

Return Parameters:

none

Notes:

Tuning on diagnostics, means that the reception of a frame consumes some more power and takes more time while the IC performs the calculations to generate the diagnostic values. The diagnostic values may be read, as part of the RX callback for instance, using the [dwt_readdiagnostics\(\)](#) API.

5.6.10 dwt_readdiagnostics

```
void dwt_readdiagnostics(dwt_diag_t * diagnostics);
```

This function reads receiver frame quality diagnostic values.

Parameters:

type	name	description
dwt_rxdiag_t*	diagnostics	Pointer to the diagnostics structure which will contain the read data.

```
typedef struct
{
    uint8_t      ipatovRxTime[5] ;
    uint8_t      ipatovRxStatus ;
    uint16_t     ipatovPOA ;
    uint8_t      stsRxTime[5] ;
    uint16_t     stsRxStatus ;
    uint16_t     stsPOA;
    uint8_t      sts2RxTime[5];
    uint16_t     sts2RxStatus;
    uint16_t     sts2POA;
    uint8_t      tdoa[5];
    int16_t      pdoa;
    int16_t      xtalOffset ;
    uint32_t     ciaDiag1 ;
    uint32_t     ipatovPeak ;
    uint32_t     ipatovPower ;
    uint32_t     ipatovF1 ;
    uint32_t     ipatovF2 ;
    uint32_t     ipatovF3 ;
    uint16_t     ipatovFpIndex ;
    uint16_t     ipatovAccumCount ;
    uint32_t     stsPeak ;
    uint16_t     stsPower ;
    uint32_t     stsF1 ;
    uint32_t     stsF2 ;
    uint32_t     stsF3 ;
    uint16_t     stsFpIndex ;
    uint16_t     stsAccumCount ;
    uint32_t     sts2Peak;
    uint16_t     sts2Power;
    uint32_t     sts2F1;
    uint32_t     sts2F2;
    uint32_t     sts2F3;
    uint16_t     sts2FpIndex;
    uint16_t     sts2AccumCount;
}dwt_rxdiag_t ;
```

Return Parameters:

none

Notes:

This function is used to read the received frame diagnostic data. They can be read after a frame is received (e.g. after DWT_SIG_RX_OKAY event reported in the RX call-back function called from [dwt_isr\(\)](#)).

Fields	Description of fields within the dwt_rxdiag_t structure
ipatovRxTime	40-bit RX timestamp from Ipatov sequence, arranged as array of octets, with least significant octet first.
ipatovRxStatus	8-bit RX status info for Ipatov sequence
ipatovPOA	POA from Ipatov preamble CIR
stsRxTime	40-bit RX timestamp from the STS, arranged as array of octets, with least significant octet first.
stsRxStatus	16-bit RX status info for STS
stsPOA	POA from STS CIR
sts2RxTime	40-bit RX timestamp from the 2 nd STS, arranged as array of octets, with least significant octet first. (this is used in PDOA mode 3, when the STS is split)
sts2RxStatus	16-bit RX status info for the 2 nd STS (this is used in PDOA mode 3, when the STS is split)
ciphe2rPOA	POA from the 2 nd STS CIR (this is used in PDOA mode 3, when the STS is split)
tdoa	TDOA from two STS RX timestamps (valid when PDOA mode 3 is configured)
pdoa	PDOA from two POAs, signed int [1:-11] in radians
xtalOffset	Estimated crystal offset of remote device. This is PPM x16, i.e. divide integer number by 16 to get the value in PPM.
ciaDiag1	Diagnostics common to both sequences
ipatovPeak	index and amplitude of peak sample in Ipatov sequence CIR
ipatovPower	channel area allows estimation of channel power for the Ipatov sequence
ipatovF1	First path amplitude for the Ipatov sequence value reporting the magnitude for the sample at the index 1 after the reported first path index value.
ipatovF2	First path amplitude for the Ipatov sequence value reporting the magnitude for the sample at the index 2 after the reported first path index value.

Fields	Description of fields within the <i>dwt_rxdiag_t</i> structure
<i>ipatovF3</i>	First path amplitude for the Ipatov sequence value reporting the magnitude for the sample at the index 3 after the reported first path index value.
<i>ipatovFpIndex</i>	First path index for Ipatov sequence
<i>ipatovAccumCount</i>	Number accumulated symbols for Ipatov sequence
<i>stsPeak</i>	index and amplitude of peak sample in STS CIR
<i>stsPower</i>	channel area allows estimation of channel power for the STS
<i>stsF1</i>	First path amplitude for the STS value reporting the magnitude for the sample at the index 1 after the reported first path index value.
<i>stsF2</i>	First path amplitude for the STS value reporting the magnitude for the sample at the index 2 after the reported first path index value.
<i>stsF3</i>	First path amplitude for the STS value reporting the magnitude for the sample at the index 3 after the reported first path index value.
<i>stsFpIndex</i>	First path index for STS
<i>stsAccumCount</i>	Number accumulated symbols for STS
<i>sts2Peak</i>	index and amplitude of peak sample in the 2 nd STS CIR, (valid when PDOA mode 3 is configured)
<i>sts2Power</i>	channel area allows estimation of channel power for the 2 nd STS, (valid when PDOA mode 3 is configured)
<i>sts2F1</i>	First path amplitude for the 2 nd STS value reporting the magnitude for the sample at the index 1 after the reported first path index value. (valid when PDOA mode 3 is configured)
<i>sts2F2</i>	First path amplitude for the 2 nd STS value reporting the magnitude for the sample at the index 2 after the reported first path index value. (valid when PDOA mode 3 is configured)
<i>sts2F3</i>	First path amplitude for the 2 nd STS value reporting the magnitude for the sample at the index 3 after the reported first path index value. (valid when PDOA mode 3 is configured)
<i>sts2FpIndex</i>	First path index for the 2 nd STS, (valid when PDOA mode 3 is configured)
<i>sts2AccumCount</i>	Number accumulated symbols for the 2 nd STS, (valid when PDOA mode 3 is configured)

5.6.11 dwt_readpdoa

```
int16_t dwt_readpdoa (void);
```

This function is used to read the PDOA result, it will return either the phase difference between Ipatov and STS POAs, or the two STS POAs, depending on the PDOA mode of operation.

Parameters:

none

Return Parameters:

type	description
int16_t	The PDOA result in radians (signed number [1:-11]). To convert to degrees: $\text{pdoa_deg} = ((\text{pdoa_rad}/1<<11))*180/\pi$

Notes:

5.6.12 dwt_configeventcounters

```
void dwt_configeventcounters (int enable);
```

This function enables event counters (TX, RX, error counters) in the IC.

Parameters:

type	name	description
int	enable	Set to 1 to clear and enable the internal digital counters. Set to 0 to disable.

Return Parameters:

none

Notes:

This function is used to enable counters that count the number of frames transmitted, and received, and various types of error events.

5.6.13 dwt_readeventcounters

```
void dwt_readeventcounters (dwt_devicecnts_t *counters);
```

This function reads the event counters (TX, RX, error counters).

Parameters:

type	name	description
dwt_devicecnts_t *	counters	Pointer to the device event counters structure.

```

Typedef struct
{
    uint16_t PHE ;           //number of received header errors
    uint16_t RSL ;           //number of received frame sync loss events
    uint16_t CRCG ;           //number of good CRC received frames
    uint16_t CRCB ;           //number of bad CRC (CRC error) received frames
    uint8_t  ARFE ;           //number of address filter rejections
    uint8_t  OVER ;           //number of RX overflows (used in double buffer
mode)
    uint16_t SFDTO ;          //number of SFD timeouts
    uint16_t PTO ;            //number of preamble timeouts
    uint8_t  RTO ;            //number of RX frame wait timeouts
    uint16_t TXF ;            //number of transmitted frames
    uint8_t  HPW ;            //number of half period warnings
    uint8_t  CRCE ;           //number of SPI CRC write errors
    uint16_t PREJ ;           //number of preamble rejections
} dwt_devicecnts_t ;

```

Return Parameters:

none

Notes:

This function is used to read the internal counters. These count the number of frames transmitted, received, and also number of errors received/detected.

Fields	Description of fields within the <i>dwt_devicecnts_t</i> structure
<i>PHE</i>	PHR error counter is a 12-bit counter of PHY header errors.
<i>RSL</i>	RSE error counter is a 12-bit counter of the non-correctable error events that can occur during Reed Solomon decoding.
<i>CRCG</i>	Frame check sequence good counter is a 12-bit counter of the frames received with good CRC/FCS sequence.
<i>CRCB</i>	Frame check sequence error counter is a 12-bit counter of the frames received with bad CRC/FCS sequence.
<i>ARFE</i>	Frame filter rejection counter is an 8-bit counter of the frames rejected by the receive frame filtering function.
<i>OVER</i>	RX overrun error counter is an 8-bit counter of receive overrun events. This is essentially a count of the reporting of overrun events, i.e. when using double buffer mode, and the receiver has already received two frames, and the host has not processed the first one. The receiver will flag an overrun when it starts receiving a third frame.

Fields	Description of fields within the <code>dwt_devicecnts_t</code> structure
<i>SFDT</i>	SFD timeout errors counter is a 12-bit counter of SFD timeout error events.
<i>PTO</i>	Preamble detection timeout event counter is a 12-bit counter of preamble detection timeout events.
<i>RTO</i>	RX frame wait timeout event counter is an 8-bit counter of receive frame wait timeout events.
<i>TXF</i>	TX frame sent counter is a 12-bit counter of transmit frames sent events. This is incremented every time a frame is sent.
<i>HPW</i>	Half period warning counter is an 8-bit counter of “Half Period Warning” events. These relate to late invocation of delayed transmission or reception functionality.
<i>CRCE</i>	SPI CRC write error is an 8-bit counter of “SPI write CRC error” events.
<i>PREJ</i>	Preamble rejection events, this is a 12-bit counter.

5.6.14 dwt_readclockoffset

```
int16_t dwt_readclockoffset(void);
```

This function can be used to read the estimated clock offset between the local clock and the remote. The value is calculated as part of the reception of the frame. It relates to last received frame and should be read after frame reception. This function is an alternative to `dwt_readcarrierintegrator()` which can also be used to calculate clock offset between two devices.

Parameters:

none

Return Parameters:

type	Description
int16_t	Signed 16-bit clock offset value. To convert to ppm the value should be divided by 2^{26} and multiplied by 10^6 .

Notes:

Positive value means that the local receiver’s clock is running faster than that of the remote transmitter.

If the CIA is not running, this function will return 0 and cannot be used to read the clock offset.

5.6.15 dwt_readcarrierintegrator

```
int32_t dwt_readcarrierintegrator(void);
```

The [*dwt_readcarrierintegrator\(\)*](#) API function reads the receiver carrier integrator value and returns it as a 32-bit signed value. The receive carrier integrator value is valid at the end of reception of a frame, (and before the receiver is re-enabled). It reflects the frequency offset of the remote transmitter with respect to the local receive clock. A positive carrier integrator value means that the local receive clock is running slower than that of the remote transmitter device.

Parameters:

none

Return Parameters:

type	Description
int32_t	Receiver carrier integrator value

Notes:

This [*dwt_readcarrierintegrator\(\)*](#) API may be called after receiving a frame to determine the clock offset of the remote transmitter the sent the frame. The receive frame should be valid (i.e. with good CRC) otherwise the clock offset information may be incorrect. The following constants are defined to allow the returned carrier integrator be converted to a frequency offset in Hertz and from that to a clock offset in PPM (which depends on the channel centre frequency): `FREQ_OFFSET_MULTIPLIER`, and `HERTZ_TO_PPM_MULTIPLIER_CHAN_5`.

The `HERTZ_TO_PPM_xxx` multipliers are negative quantities, so when the resultant clock offsets are positive it means that the local receiver's clock is running slower than that of the remote transmitter.

Example code:

```
int32_t ci ;
float clockOffsetHertz ;
float clockOffsetPPM ;

ci = dwt_readcarrierintegrator() ; // Read carrier integrator value

// at 6.81Mb/s data rate convert carrier integrator to clock offset in Hz.
clockOffsetHertz = ci * FREQ_OFFSET_MULTIPLIER;

// On channel 5 convert this to clock offset in PPM.
clockOffsetPPM = clockOffsetHertz * and HERTZ_TO_PPM_MULTIPLIER_CHAN_5 ;
```

5.6.16 dwt_readstsquality

```
int dwt_readstsquality (int16_t *rxSTSQualityIndex);
```

This function may be used in any STS mode. It reads the STS quality index and also returns an indication of whether the STS reception quality is good or bad. After a frame is received the [*dwt_readstsquality\(\)*](#) API can be used to assess the quality of the STS and hence decide whether to trust the RX timestamp.

The STS is considered good when the (STS) quality index is greater than a specified threshold value, which is a percentage of the configured STS length. These thresholds have been set as hard coded values in the device driver code.

Parameters :

Type	Name	description
int16_t*	rxSTSQualityIndex	The reported quality index will be stored in this parameter on function exit.

Return Parameters :

type	Description
int	This value is the STS quality index minus the threshold value which depends on the configured STS PRF and the configured STS length. If this return value is > 0 this indicates that the STS quality is good, however if this return value is negative this indicates that the received frame has bad quality STS and the resulting timestamps are less trustworthy

Notes :**5.6.17 dwt_readstsstatus**

```
int dwt_readstsstatus(uint16_t* stsStatus, int sts_num);
```

This function may be used in any STS mode. It will read the STS status register in order to show if there are any errors present in the STS signals. It can be used in conjunction with the [dwt_readstsquality\(\)](#) API after a packet/frame is received.

A 16-bit buffer is passed into the function and is populated with a '1' or '0' depending on whether the 9 different STS statuses are set high or not. The remaining upper 7 bits of the 16 bits are ignored. Only bits 8 through to 0 are set.

Parameters :

Type	Name	description
uint16_t*	stsStatus	This 16-bit buffer is populated with the various STS statuses that are described in the CY1_TOA_HI register.
int	sts_num	This parameter is used to select which STS packet/frame to analyse the status of. In regular operation, there will only be one STS packet/frame to analyse. However, when PDOA Mode 3 is used, there are two separate STS packets/signals to analyse. '0' will select the first STS while '1' will select the second STS.

Return Parameters :

type	Description
------	-------------

int	DWT_SUCCESS is returned for good/valid STS status. Otherwise, DWT_ERROR is returned for a bad STS status.
-----	---

Notes:

The available STS statuses that are available to read as part of the [stsStatus](#) are described in the table below:

Table 21: stsStatus values

Buffer Bits	Default Value	Description
stsStatus[8]	0x0	Peak growth rate warning
stsStatus[7]	0x0	ADC count warning
stsStatus[6]	0x0	SFD count warning
stsStatus[5]	0x0	Late first path estimation
stsStatus[4]	0x0	Late coarse estimation
stsStatus[3]	0x0	Coarse estimation empty
stsStatus[2]	0x0	High noise threshold
stsStatus[1]	0x0	Non-triangle
stsStatus[0]	0x0	Logistic regression failed

5.7 Temperate and voltage reading APIs**5.7.1 dwt_readtempvbat**

```
uint16_t dwt_readtempvbat(void);
```

This function reads the temperature and battery voltage. Note: the DW3000 needs to be in IDLE_PLL mode or the call will return 0.

Parameters:

none

Return Parameters:

type	description
uint16_t	The low 8-bits are voltage value, and the high 8-bits are temperature value.

Notes:

This function can be called to read the battery voltage and temperature. It enables the IC's internal convertors to sample the current IC temperature and battery. Must be called when DW3000 is in IDLE.

5.7.2 dwt_converttrawtemperature

```
float dwt_converttrawtemperature(uint8_t raw_temp);
```

This function takes a raw temperature value and applies the conversion factor to return a temperature in degrees.

Parameters:

type	name	description
uint8_t	raw_temp	Raw 8-bit temperature value, as returned by dwt_readtempvbat()

Return Parameters:

type	description
float	The temperature value in degrees.

Notes:

This function is called to convert the raw IC temperature to degrees, the conversion is given by:

$$\text{Temperature (}^{\circ}\text{C)} = (\text{SAR_LTEMP} - \text{OTP_READ(Vtemp @ 23}^{\circ}\text{C)}) \times 1.05 + 20$$

5.7.3 dwt_convertdegtemporaw

```
uint8_t dwt_convertdegtemporaw(int16_t externaltemp);
```

This function takes an externally measured temperature in 10ths of degrees Celsius and converts it into IC temperature units, as if produced by the SAR A/D. The [dwt_initilise\(\) API](#) needs to be called before calling this [dwt_convertdegtemporaw\(\)](#) API to ensure internal structure contains the SAR_LTEMP (reference measured @ 23 °C) value from OTP.

Parameters:

type	name	description
int16_t	externaltemp	Externally measured temperature value, in 10ths of °C.

Return Parameters:

type	description
uint8_t	The temperature value in DW IC temperature units.

Notes:

5.7.4 dwt_converttrawvoltage

```
float dwt_converttrawvoltage (uint8_t raw_volt);
```

This function takes a raw voltage value and applies the conversion factor to return a voltage in volts.

Parameters:

type	name	description
uint8_t	raw_volt	Raw 8-bit voltage value, as returned by dwt_readtempvbat()

Return Parameters:

type	description
float	The voltage value in volts.

Notes:

This function is called to convert the raw IC voltage to volts, the conversion is given by:

$$\text{Voltage (V)} = ((\text{SAR_LVBAT} - \text{OTP_READ}(\text{Vmeas @ 3.0 V})) * 0.4 * 16 / 255) + 3.0$$

5.7.5 dwt_convertvoltstoraw

```
float dwt_convertvoltstoraw (int32_t externalmvolt);
```

This function takes a voltage value in millivolts and converts it into “raw” IC voltage units, as if produced by the SAR A/D. The [dwt_initilise\(\) API](#) needs to be called before calling this [dwt_convertvoltstoraw\(\)](#) API to ensure that the local data structure contains the SAR_LVBAT (reference measured @ 3.3 V) value from OTP.

Parameters:

type	name	description
int32_t	externalmvolt	This is a true voltage in millivolts to convert to IC units

Return Parameters:

type	description
uint8_t	The voltage value in DW IC voltage units.

Notes:

5.8 OTP and AON access APIs

5.8.1 dwt_otpread

```
void dwt_otpread(uint32_t address, uint32_t *array, uint8_t length);
```

This function is used to read a number (given by length) of 32-bit values from the IC's OTP memory, starting at given address. The given array will contain the read values.

Parameters :

type	name	description
uint32_t	address	This is starting address in the OTP memory from which to read
uint16_t*	array	This is the 32-bit array that will hold the read values. It should be of at least <i>length</i> 32-bit words long.
uint8_t	length	The number of values to read

Return Parameters :

none

Notes :

none

5.8.2 dwt_otpwritandverify

```
int dwt_otpwritandverify(uint32_t value, uint16_t address);
```

This function is used to program 32-bit value into OTP memory.

Parameters :

type	name	description
uint32_t	value	this is the 32-bit value to be programmed into OTP memory
uint16_t	address	this is the 16-bit OTP memory address into which the 32-bit value is programmed

Return Parameters :

type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes :

The IC has a small amount of one-time-programmable (OTP) memory intended for device specific configuration or calibration data. Some areas of the OTP memory are used to save device calibration values determined during IC testing, while other OTP memory locations are intended to be set by the customer during module manufacture and test.

Programming OTP memory is a one-time only activity, any values programmed in error cannot be corrected. Also, please take care when programming OTP memory to only write to the designated areas – programming elsewhere may permanently damage the IC's ability to function normally.

The OTP memory locations are as defined in Table 22. The OTP memory locations are each 32-bits wide; OTP addresses are word addresses, so each increment of address specifies a different 32-bit word.

Table 22: OTP memory map

The QSR (“Special function register”) is a 32-bit segment of OTP that is directly readable via the register interface upon power up. To program the SR register follow the normal OTP programming method but set the OTP address to 0x60. As this is part of OTP boot sequence the new value will be present in the QSR register following the next boot up sequence.

For more information on OTP memory programming please consult the User Manual [2] and Data Sheet [1].

5.8.3 dwt_aon_read

```
uint8_t dwt_aon_read (uint16_t aon_address);
```

The [*dwt_calibratesleepcnt\(\)*](#) function reads from the AON memory. It returns an 8-bit read from the given AON memory address.

Parameters:

type	name	description
uint16_t	aon_address	This is the address of the memory location to read.

Return Parameters:

type	description
uint8_t	8-bit value of the AON memory address given.

Notes:

This function allows the user to read addresses from AON memory. Please see the implementation of [*dwt_calibratesleepcnt\(\)*](#) for an example of how this function is utilised.

5.8.4 dwt_aon_write

```
void dwt_aon_read (uint16_t aon_address , uint8_t aon_write_data);
```

The [*dwt_calibratesleepcnt\(\)*](#) function writes to the AON memory given a 16-bit address and 8-bit value. It has no return values.

Parameters:

Type	name	description
uint16_t	aon_address	This is the address of the memory location to write to.
uint8_t	aon_write_data	This is the 8-bit value that is written to the specified AON address.

Return Parameters:

none

Notes:

This function allows the user to write a value to AON memory. Please see the implementation of [*dwt_calibratesleepcnt\(\)*](#) for an example of how this function is utilised.

5.8.5 dwt_clearaonconfig

```
void dwt_clearaonconfig(void);
```

This function allows the user to clear the AON configuration. This will clear any previously programmed configurations such as AON on-wake / wake-up configurations. Default values will be restored.

Parameters:

none

Return Parameters:

none

Notes:

When this function is called, anything set in the AON_DIG_CFG register will be cleared. The same applies for the ANA_CFG register. The default configuration will be loaded into the AON_CTRL register also.

5.9 TX test APIs

5.9.1 dwt_setfinegraintxseq

```
void dwt_setfinegraintxseq(int enable);
```

This is used to activate/deactivate fine grain TX sequencing. In some applications/use cases the fine grain TX sequencing needs to be disabled, e.g. continuous wave mode or when driving an external PA. Please refer to [2] for more details about those modes.

Parameters:

type	name	description
int	enable	Set to 1 to enable fine grain TX sequencing, 0 to disable it.

Return Parameters:

none

none

5.9.2 dwt_setxtaltrim

```
void dwt_setxtaltrim(uint8_t value);
```

This function writes the crystal trim value parameter into the IC crystal trimming register.

Parameters:

type	name	description
uint8_t	value	Crystal trim value (in range 0x0 to 0x7F, 127 steps (~1.5ppm per step)).

Return Parameters:

none

Notes:

This function can be called any time to set the crystal trim register value. This is used to fine tune and adjust the XTAL frequency. Better long-range performance may be achieved when crystals are more closely matched. Crystal trimming may allow this without using expensive TCXO devices. Please consult the User Manual [2], Data Sheet [1] and application notes available on www.decawave.com.

5.9.3 dwt_configcwmode

```
void dwt_configcwmode(uint8_t channel);
```

This function configures the device to transmit a Continuous Wave (CW) at a specified channel frequency. This may be of use as part of crystal trimming procedure. Please consult with Decawave's applications support team for details of crystal trimming procedures and considerations.

Parameters:

type	name	description
uint8_t	channel	This is the channel: 5 or 9.

Return Parameters:

none

Notes:

Example code of how to use this function in conjunction with [dwt_setxtaltrim\(\)](#) function is given by the Example 04a: continuous wave mode sample example in the API package [5]

5.9.4 dwt_configcontinuousframemode

```
void dwt_configcontinuousframemode(uint32_t framerepetitionrate, uint8_t channel);
```

This function configures continuous frame mode. This facilitates measurement of the power in the transmitted spectrum.

Parameters:

type	name	description
uint32_t	framerepetitionrate	This is a 32-bit value that is used to set the interval between transmissions. The minimum value is 4. The units are approximately 8 ns. (or more precisely $512/(499.2e6*128)$ seconds)).

uint8_t	channel	This is the channel: 5 or 9.
---------	---------	------------------------------

Return Parameters:

none

Notes:

This function is used to configure continuous frame (transmit power spectrum test) mode, used in TX power spectrum measurements. This test mode is provided to help support regulatory approvals spectral testing. Please consult with Decawave's applications support team for details of regulatory approvals considerations. The [dwt_configcontinuousframemode\(\)](#) function enables a repeating transmission of the data from the transmit buffer. To use this test mode, the operating channel, preamble code, data length, offset, etc. should all be set-up as if for a normal transmission.

The [framerepetitionrate](#) parameter value is programmed in units of one quarter of the 499.2 MHz fundamental frequency, (~ 8 ns). To send one frame per millisecond, a value of 124800 or 0x0001E780 should be set. A value <4 will not work properly, and a time value less than the frame length will cause the frames to be sent back-to-back without any pause.

We expect there to be two use cases for the [dwt_configcontinuousframemode\(\)](#) function:

- (a) Testing to figure out the TX power/pulse width to meet the regulations.
- (b) In the approvals house to enable the spectral test.

To end the test and return to normal operation the device can be rest with [dwt_softreset\(\)](#) function.

Please see Example 04b: continuous frame mode, of the API package [5] for an example of the use of this API function.

5.9.5 dwt_calcbandwidthadj

```
uint8_t dwt_calcbandwidthadj(uint16_t target_count, int chan);
```

This function runs a bandwidth compensation algorithm that adjusts the bandwidth of the output spectrum to correct for the effects of different temperatures. This ensures that the bandwidth is constant at any temperature. The target count parameter is a reference value taken at a known temperature for a known good bandwidth using the [dwt_calcpcount\(\)](#) API call, which relates directly to the bandwidth of the spectrum.

Parameters:

Type	name	description
uint16_t	target_count	This is a 16-bit value that is used by the IC to calculate a bandwidth adjust value
int	chan	This is the channel: 5 or 9

Return Parameters:

type	Description
------	-------------

uint8_t	This is an 8-bit value that represents a pulse generator delay (PG_DELAY) value
---------	---

Notes :

See the app note in [4] for more details. The return value is automatically set into DW3000 PG delay register, but it is also returned here so host knows what it was set to.

5.9.6 dwt_calcpgcount

```
uint16_t dwt_calcpgcount(uint8_t pgdly, int chan);
```

This function returns a pulse generator count value that is used as a reference for bandwidth compensation over temperature. The pulse generator delay value that is passed in should be the current bandwidth setting.

Parameters :

Type	Name	description
uint8_t	pgdly	This is an 8-bit value representing the current pulse generator delay for the current bandwidth setting
int	chan	This is the channel: 5 or 9

Return Parameters :

type	Description
uint16_t	This is a 16-bit value that represents the pulse generator count value for the current pulse generator delay. It is directly related to the bandwidth.

Notes :

See the app note in [4] for more details. The return value should be stored as a reference to be used with [dwt_calcbandwidthadj\(\)](#).

5.10 AES APIs**5.10.1 dwt_configure_aes**

```
void dwt_configure_aes(const dwt_aes_config_t *pCfg)
```

This function initializes the AES_CFG register that is responsible for the tag size, key size, etc.

Parameters :

Type	Name	description
dwt_aes_config_t	pCfg	This struct contains all the needed fields for initialization of this reg.

```
typedef struct {
```

```

dwt_aes_key_otp_type_e  aes_key_otp_type;

dwt_aes_core_type_e     aes_core_type;  //!< Core type

dwt_mic_size_e          mic;            //!< Message integrity code
                                   //size

dwt_aes_key_src_e       key_src;        //!< Location of the key:
                                   //either as programmed in
                                   //registers(128 bit) or in the
                                   //RAM

dwt_aes_key_load_e      key_load;       //!< Loads key from RAM

uint8_t                 key_addr;       //!< Address offset of AES key
                                   //in AES key RAM

dwt_aes_key_size_e      key_size;       //!< AES key length
                                   //configuration corresponding
                                   //to AES_KEY_128/192/256bit

dwt_aes_mode_e          mode;          //!< Operation type
                                   //encrypt/decrypt

} dwt_aes_config_t ;

```

Return Parameters:

none

Notes:

Further information on the structures that make up the `dwt_aes_config_t` structure can be found within the source code.

5.10.2 dwt_set_keyreg_128

```
void dwt_set_keyreg_128(const dwt_aes_key_t *key);
```

This function sets the AES key – 128 bits. It updates the AES_KEY0 – AES_KEY2.

Parameters:

Type	Name	description
dwt_aes_key_t	key	This struct contains all the keys values that is needed for the initialization.

Return Parameters:

none

5.10.3 dwt_do_aes

```
int8_t dwt_do_aes(dwt_aes_job_t *job, dwt_aes_core_type_e core_type)
```

This function responsible for data encryption/decryption, filling the relevant buffer (in case of decryption) or updating the TX buffer with encrypted data (in case of encryption). The function also checks for errors and updates the nonce.

Parameters:

Type	Name	description
dwt_aes_job_t	job	This is a struct pointer that contains the info and buffers for encryption/decryption, header, payload, nonce, ...
dwt_aes_core_type_e	core_type	This option refers to the AES core type used by the IC. The options are either GCM core type (0) or CCM core type (1).

Return Parameters:

type	Description
int8_t	Negative value on error or AES_STS reg value. AES_STS reg value will be checked in the calling function

5.10.4 dwt_mic_size_from_bytes

dwt_mic_size_e dwt_mic_size_from_bytes(uint8_t mic_size_in_bytes)

This function gets mic size in bytes and returns the MIC size to fit into AES_CFG-AES_TAG_SIZE reg.

Parameters:

Type	Name	description
uint8_t	mic_size_in_bytes	Mic size in bytes.

Return Parameters:

dwt_mic_size_e – Enum that contains the right value for the AES reg.

5.11 SPI driver functions

These functions are platform specific SPI read and write functions, external to the driver code, used by the device driver to send and receive data over the SPI interface to and from the IC. The device driver abstracts the target SPI device by calling it through generic functions [writetospi\(\)](#) and [readfromspi\(\)](#). In porting the device driver, to different target hardware, the body of these SPI functions should be written, re-written, or provided in the target specific code to drive the target microcontroller device's physical SPI hardware. The initialisation of the target host controller's physical SPI interface mode and its data rate is considered to be part of the target system and is done in the host code outside of the device driver functions.

5.11.1 writetospi

```
int writetospi (uint16_t hLen, const uint8_t *hbuff, uint32_t bLen, const uint8_t *buffer);
```

This function is called by the device driver code (from the [dwt_writetodevice\(\)](#) function) when it wants to write to the IC's SPI interface (registers) over the SPI bus.

Parameters:

type	name	Description
uint16_t	hLen	This is gives the length of the header buffer (hbuff)
uint8_t*	hbuff	This is a pointer to the header buffer byte array. The LSB is the first element.
uint32_t	bLen	This is gives the length of the data buffer (buffer), to write.
uint8_t*	buffer	This is a pointer to the data buffer byte array. The LSB is the first element. This holds the data to write.

Return Parameters:

Type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

The return values can be used to notify the upper application layer that there was a problem with SPI write. The [dwt_writetodevice\(\)](#) function has a return value, however it should be noted that the device driver itself does not take any notice of success/error return value but instead assumes that SPI accesses succeed without error.

5.11.2 writetospiwithcrc

```
int writetospiwithcrc(uint16_t hLen, const uint8_t *hbuff, uint32_t bLen, const uint8_t *buffer,
uint8_t crc);
```

When the IC is configured to use SPI with 8-bit CRC mode, this function is called by the device driver code (from the [dwt_writetodevice\(\)](#) function) to write to the SPI interface (registers) over the SPI bus. In this mode the IC is expecting an 8-bit CRC to be sent as the last byte of the write SPI transaction. If the CRC it receives from the host does not match a CRC it generates internally, then the IC will set SPI CRC error bit which will generate an interrupt if this status event has been masked enabled by the [dwt_setinterrupt\(\)](#) function.

Parameters :

type	name	Description
uint16_t	hLen	This is gives the length of the header buffer (<i>hbuff</i>)
uint8_t*	hbuff	This is a pointer to the header buffer byte array. The LSB is the first element.
uint32_t	bLen	This is gives the length of the data buffer (<i>buffer</i>), to write.
uint8_t*	buffer	This is a pointer to the data buffer byte array. The LSB is the first element. This holds the data to write.
uint8_t	crc	This is the 8-bit CRC generated from the header and data bytes, which needs to be at the end of the SPI transaction

Return Parameters :

Type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes :

The return values can be used to notify the upper application layer that there was a problem with SPI write. The [dwt_writetodevice\(\)](#) function has a return value, however it should be noted that the device driver itself does not take any notice of success/error return value but instead assumes that all SPI accesses succeed without error.

5.11.3 readfromspi

```
int readfromspi (uint16_t hLen, const uint8_t *hbuff, uint32_t bLen, uint8_t *buffer);
```

This function is called by the device driver code (from the [dwt_readfromdevice\(\)](#) function) when it wants to read from the IC's SPI interface (registers) over the SPI bus.

Parameters :

type	name	description
uint16_t	hLen	This is gives the length of the header buffer (<i>hbuff</i>)
uint8_t*	hbuff	This is a pointer to the header buffer byte array. The LSB is the first element.
uint32_t	bLen	This is gives the number of bytes to read.
uint8_t*	buffer	This is a pointer to the data buffer byte array. The LSB is the first element. This holds the data being read.

Return Parameters:

Type	description
int	Return values can be either DWT_SUCCESS = 0 or DWT_ERROR = -1.

Notes:

The return values can be used to notify the upper application layer that there was a problem with SPI read. The [dwt_readfromdevice\(\)](#) function has a return parameter, however it should be noted that the device driver itself does not take any notice of success/error return value but instead assumes that each SPI access succeeds without error.

5.12 Mutual-exclusion API functions

The purpose of these functions is to provide for microprocessor interrupt enable/disable, which is used for ensuring mutual exclusion from critical sections in the device driver code where interrupts and background processing may interact. The only use made of this is to ensure SPI accesses are non-interruptible.

The mutual exclusion API functions are [decamutexon\(\)](#) and [decamutexoff\(\)](#). These are external to the driver code but used by the device driver when it wants to ensure mutual exclusion from critical sections. This usage is kept to a minimum and the disable period is also kept to a minimum (but is dependent on the SPI data rate). A blanket interrupt disable may be the easiest way to provide this mutual exclusion functionality in the target system, but at a minimum those interrupts coming from the device should be disabled/re-enabled by this activity.

In implementing the [decamutexon\(\)](#) and [decamutexoff\(\)](#) functions in a particular microprocessor system, the implementer may choose to use `#defines` to map these calls transparently to the target system. Alternatively the appropriate code may be embedded in the functions provided in the [deca_mutex.c](#) source file.

5.12.1 decamutexon

```
decalrqStatus_t decamutexon (void);
```

This function is used to turn on mutual exclusion (e.g. by disabling interrupts). **This is called at the start of the critical section of SPI access.** The [decamutexon\(\)](#) function should operate to read the

current system interrupt status in the target microcontroller system's interrupt handling logic with respect to the handling of the IC's interrupt. Let's call this "IRQ_State" Then it should disable the interrupt relating to the IC, and then return the original IRQ_State.

Parameters:

none

Return Parameters:

Type	Description
decalrqStatus_t	This is the state of the target microcontroller's interrupt logic with respect to the handling the IC's interrupt, as it was on entry to the decamutexon() function before it did any interrupt disabling.

```
Typedef int decalrqStatus_t ;
```

Notes:

The [decamutexon\(\)](#) function returns the IC's interrupt status, which can be noted and appropriate action taken. The returned status is intended to be used in the call to [decamutexoff\(\)](#) function to be used to restore the interrupt enable status to its original pre-[decamutexon\(\)](#) state.

5.12.2 decamutexoff

```
void decamutexoff (decalrqStatus_t state);
```

This function is used to restore the IC's interrupt state as returned by [decamutexon\(\)](#) function. It is used to turn off mutual exclusion (e.g. by enabling interrupts if appropriate). **This is called at the end of the critical section of SPI access.** The [decamutexoff\(\)](#) function should operate to restore the system interrupt status in the target microcontroller system's interrupt handling logic to the state indicated by the input "IRQ_State" parameter, [state](#).

Parameters:

type	name	description
decalrqStatus_t	state	This is the state of the target microcontroller's interrupt logic with respect to the handling of the IC's interrupt, as it was on entry to the decamutexon() function before it did any interrupt disabling.

Return Parameters:

none

Notes:

The state parameter passed into [decamutexoff\(\)](#) function should be used to appropriately set/restore the system interrupt status in the target microcontroller system's interrupt handling logic.

5.13 Sleep function

The purpose of this function is to provide a platform dependent implementation of sleep feature, i.e. waiting for a certain amount of time before proceeding with the application's next step.

This is an external function used by the driver code to wait for the end of a process, e.g. the stabilization of a clock or the completion of a write command. This function is provided in the [deca_sleep.c](#) source file.

5.13.1 deca_sleep

```
void deca_sleep (unsigned int time_ms);
```

This function is used to wait for a given amount of time before proceeding to the next step of the calling function.

Parameters :

type	name	description
unsigned int	time_ms	The amount of time to wait, expressed in milliseconds.

Return Parameters :

None

Notes :

The implementation provided here is designed for a simple single-threaded system and is blocking, i.e. it will prevent the system from doing anything else during the waiting time.

5.14 Subsidiary functions

These functions are used to provide low-level access to individually numbered registers and buffers (or register files). These may be needed to access IC functionality not included in the main API functions above.

5.14.1 dwt_writetodevice

```
dwt_writetodevice(uint32_t regID, uint16_t index, uint16_t length, const uint8_t *buffer);
```

This function is used to write to the IC's registers and buffers. The [regID](#) specifies the main address of the register or parameter block being accessed, e.g. a [regID](#) of DX_TIME selects the delay TX or RX start time register. The [index](#) parameter selects a sub-address within the register file. An [index](#) value of 0 is used for most of the accesses employed in the device driver. The [length](#) parameter specifies the number of bytes to write, and the [buffer](#) parameter points at the bytes to actually write. If DWT_API_ERROR_CHECK code switch is defined, this function will check input parameters and assert if an error is detected.

5.14.2 dwt_readfromdevice

```
void dwt_readfromdevice(uint32_t regID, uint16_t index, uint16_t length, uint8_t *buffer);
```

This function is used to read from the IC's registers and buffers. The parameters are the same as for the [dwt_writetodevice](#) function above except that the *buffer* parameter points at a location where the bytes being read are placed by the function call. If DWT_API_ERROR_CHECK code switch is defined, this function will check input parameters and assert if an error is detected. It is up to the developer to ensure that the assert macro is correctly enabled in order to trap any error conditions that arise.

5.14.3 dwt_read32bitreg

```
uint32_t dwt_read32bitreg(int regFileID);
```

This function is used to read 32-bit IC registers.

5.14.4 dwt_read32bitoffsetreg

```
uint32_t dwt_read32bitoffsetreg(int regFileID, int regOffset);
```

This function is used to read a 32-bit IC register that is part of a sub-addressed block.

5.14.5 dwt_write32bitreg

```
void dwt_write32bitreg(int regFileID, uint32_t regval);
```

This function is used to write a 32-bit IC register that is part of a sub-addressed block.

5.14.6 dwt_write32bitoffsetreg

```
void dwt_write32bitoffsetreg(int regFileID, int regOffset, uint32_t regval);
```

This function is used to write to a 32-bit IC register that is part of a sub-addressed block.

5.14.7 dwt_read16bitoffsetreg

```
uint16_t dwt_read16bitoffsetreg(int regFileID, int regOffset);
```

This function is used to read a 16-bit IC register that is part of a sub-addressed block.

5.14.8 dwt_write16bitoffsetreg

```
void dwt_write16bitoffsetreg(int regFileID, int regOffset, uint16_t regval);
```

This function is used to write a 16-bit IC register that is part of a sub-addressed block.

5.14.9 dwt_read8bitoffsetreg

```
uint8_t dwt_read8bitoffsetreg(int regFileID, int regOffset);
```

This function is used to read an 8-bit IC register that is part of a sub-addressed block.

5.14.10 dwt_write8bitoffsetreg

```
void dwt_write8bitoffsetreg(int regFileID, int regOffset, uint8_t regval);
```

This function is used to write an 8-bit IC register that is part of a sub-addressed block.

5.14.11 dwt_modify32bitoffsetreg

```
void dwt_write32bitoffsetreg(int regFileID, int regOffset, uint32_t andmask, uint32_t ormask);
```

This function is used to clear or set individual bits in a 32-bit register. The andmask will be AND-ed with the register value, and the ormask OR-ed. Single or multiple bits can be set in a single SPI transaction.

5.14.12 dwt_modify16bitoffsetreg

```
void dwt_write16bitoffsetreg(int regFileID, int regOffset, uint16_t andmask, uint16_t ormask);
```

This function is used to clear or set individual bits in a 16-bit register. The andmask will be AND-ed with the register value, and the ormask OR-ed. Single or multiple bits can be set in a single SPI transaction.

5.14.13 dwt_modify8bitoffsetreg

```
void dwt_modify8bitoffsetreg(int regFileID, int regOffset, uint8_t andmask, uint8_t ormask);
```

This function is used to clear or set individual bits in an 8-bit register. The andmask will be AND-ed with the register value, and the ormask OR-ed. Single or multiple bits can be set in a single SPI transaction.

5.14.14 dwt_writefastCMD

```
void dwt_writefastCMD(int cmd);
```

This function is used to write a single byte special 5-bit command word to the device. The supported commands are listed below:

Table 23: List of supported commands

Command ID	Value	Description
CMD_TXRXOFF	0x0	Puts the device into IDLE state and clears any events.
CMD_TX	0x1	Immediate start TX
CMD_RX	0x2	Immediate RX on
CMD_DTX	0x3	Delayed TX w.r.t. DX_TIME
CMD_DRX	0x4	Delayed RX w.r.t. DX_TIME
CMD_DTX_TS	0x5	Delayed TX w.r.t. TX timestamp + DX_TIME
CMD_DRX_TS	0x6	Delayed RX w.r.t. TX timestamp + DX_TIME

Command ID	Value	Description
CMD_DTX_RS	0x7	Delayed TX w.r.t. RX timestamp + DX_TIME
CMD_DRX_RS	0x8	Delayed RX w.r.t. RX timestamp + DX_TIME
CMD_DTX_REF	0x9	Delayed TX w.r.t. REF_TIME + DX_TIME
CMD_DRX_REF	0xA	Delayed RX w.r.t. REF_TIME + DX_TIME
CMD_CCA_TX	0xB	TX frame if no preamble detected
CMD_TX_W4R	0xC	Immediate start TX, then enable receiver
CMD_DTX_W4R	0xD	Delayed TX w.r.t. DX_TIME, then enable receiver
CMD_DTX_TS_W4R	0xE	Delayed TX w.r.t. TX timestamp + DX_TIME, then enable receiver
CMD_DTX_RS_W4R	0xF	Delayed TX w.r.t. RX timestamp + DX_TIME, then enable receiver
CMD_DTX_REF_W4R	0x10	Delayed TX w.r.t. REF_TIME + DX_TIME, then enable receiver
CMD_CCA_TX_W4R	0x11	TX frame if no preamble detected, then enable receiver
CMD_CLR_IRQS	0x12	Clear all interrupt events

6 APPENDIX 1 – SIMPLE EXAMPLES

The API package [5] provides, along with the IC driver itself, a set of simple example applications designed to show how to achieve a number of basic features of the IC like sending a frame, receiving a frame, putting the IC to sleep, etc.

All these examples have been designed to be as simple as possible. The main idea is to make the code self-explanatory and include the least possible amount of code not directly involved in the achievement of the example-related feature. One of the consequences of this design is that the examples output very little (or even no) debug information and are designed so that the application flow can be followed using a debugger to examine run-time operations.

On the hardware side, the examples have been designed to run on an DW3000 C0 Arduino-type shield. The base layers included in this package (see detail below) provide specific implementations for this HW.

6.1 Package structure

The folder structure of the package is the following:

Figure 7: API package structure tree

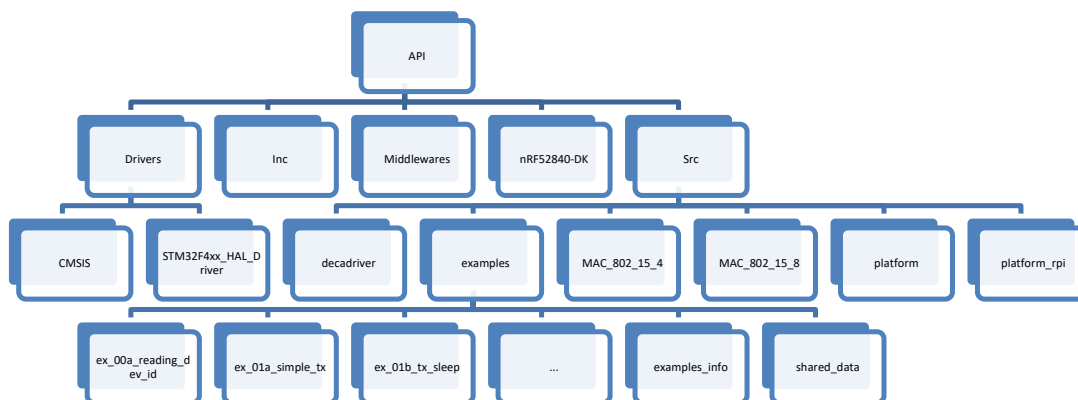

Table 24: API package structure

Folder				Brief description
API				Root directory of DW3000 C0 API and test examples.
	Drivers			Directory containing drivers that are required for STM platform.
		CMSIS		

	└──	STM32F4xx_ HAL_Driver		
└──	Inc			Various include files required for STM platform.
└──	Middlewares			Middlewares required for STM platform.
└──	nRF52840-DK			Directory containing SEGGER IDE build files for Nordic platform.
└──	Src			Main source directory of Decawave/Qorvo API code + simple examples.
	└──	decadriver		Source files for the DW3000 driver (API code).
	└──	examples		Examples directory containing various simple examples.
		└──	ex_00a_reading_dev_id	Read Device ID example code.
		└──	ex_01a_simple_tx	Simple TX example code.
		└──	ex_01b_tx_sleep	TX Sleep example code.
		└──	...	Additional
		└──	examples_info	
		└──	shared_data	
	└──	MAC_802_15_4		MAC layer IEEE 802.15.4 code.
	└──	MAC_802_15_8		MAC layer IEEE 802.15.8 code.
	└──	platform		Platform dependent source code for STM build.
	└──	platform_rpi		Platform dependent source code for Raspberry Pi build.

All example applications are named after the feature or set of features they implement.

6.2 Building and running the examples

All examples provide a specific `ex_<example number>_<example name>.c` source file with a single project build configuration. To build and run the code, just unzip the source code and import the project as “Existing Projects into Workspace” into your ST Workbench IDE. If ST Workbench IDE is already installed on your machine, you should be able to simply double-click the “.cproject” file and the project will load into the IDE.

Once the project is loaded into the IDE, select the example to build by editing the “..\API\Src\example_selection.h” header file. Each simple example has a corresponding “#define” (pre-processor macro definition) in this header file. For example, to build the “ex_00a_reading_dev_id” simple example, the “//” before the “#define TEST_READING_DEV_ID” would need to be removed. By default, each of the pre-processor macro definitions that correspond to a simple example are commented out (with a “//” in front of each line). If there is any confusion as to which pre-processor macro definition needs to be enabled for a particular simple example, simply look at the source code for the simple example in question. It will have an “#if

defined(<example macro definition>)" near the top of the source file. This is the macro definition to enable in the "example_selection.h" file to build that simple example.

ST Workbench IDE (SW4STM32) and CubeMX project generator can be downloaded from ST website. [6]

6.3 Examples list

As all examples have been designed to be self-explanatory and quite straightforward to read. The following is a list of all the examples provided with a brief description of the function of each.

6.3.1 Example 00a: reading device ID

This example is the most basic example which just reads the DW3000 device ID register. This can be used to test that the SPI communications between host MCU and DW3000 are working correctly.

6.3.2 Example 01a: simple TX

This example application repeatedly sends a hard-coded standard blink frame. Hard-coded delay between frames is 1 second.

6.3.3 Example 01b: TX with sleep

This is a variation of example 1a, where the IC is commanded to sleep and then awoken after the delay between each frame.

There are two flavours of this example "tx_sleep" and "sleep_idleRC". In the latter the device remains in IDLE_RC state after wakeup, and only transitions to IDLE prior to transmission of the message, staying in IDLE_RC during the programming of TX data and frame control means DW3000 is in a lower power state, and consumes less power than if it was in IDLE state (as in the former example).

6.3.4 Example 01c: TX with auto sleep

This is a variation of example 1b where the IC automatically goes to sleep after the transmission of a frame. The IC is still commanded to wake up after the desired sleep period has elapsed before sending the next frame.

6.3.5 Example 01d: TX with timed sleep

This is a variation of example 1c where the IC automatically wakes up using an internal sleep timer. Before the IC is put to sleep for the first time, the internal low-power oscillator driving the sleep counter is calibrated so that the desired sleep time can be properly set through the sleep timer counter.

6.3.6 Example 01e: TX with CCA

Here we implement a simple Clear Channel Assessment (CCA) mechanism before frame transmission. The CCA can be used to avoid collisions with other frames on the air.

Note this example is not doing CCA the way a continuous carrier radio would do it by looking for energy/carrier in the band. It is only looking for preamble so will not detect PHR or data phases of the frame. In a UWB data network it is advised to also do a random back-off before re-transmission in the event of not receiving acknowledgement to a data frame transmission.

6.3.7 Example 01g: simple TX with STS

This example is very similar to Example 1a, 6.3.1 above, except that it is using STS configuration.

6.3.8 Example 01h: simple TX for PDOA

This example is very similar to Example 1a, 6.3.1 above, except that it is using TX configuration for PDOA.

6.3.9 Example 01i: simple TX with AES

This example is very similar to Example 1a, 6.3.1 above, except that it is using AES encryption of the data payload (of 802.15.8 sample frame). The encrypted data is fixed bytes array, but the header is changing according to the nonce (changing according to counter) and frame sequence number. This payload is then decrypted by the 6.3.16 companion example.

6.3.10 Example 02a: simple RX

This example application waits indefinitely for an incoming frame. When a frame is received, it is read into a local buffer where it can be examined and then the application re-enables the receiver to start waiting for another frame. It is intended that the simple TX examples (like that in [6.3.1 above](#)) should be used as a source of frames when running these simple RX examples.

6.3.11 Example 02c: simple RX with diagnostics

This is a variation of example 2a where RX frame diagnostic information (first path index, channel impulse response power) and accumulator (channel impulse response) values are read for each received frame. This information is read into a local structure where it can be examined.

6.3.12 Example 02d: RX SNIFF mode

This is a variation of example 2a where the RX SNIFF mode of DW3000 is used. When the receiver is enabled, it begins preamble-hunt mode with the receiver on. In SNIFF mode, the receiver is not on all the time, but is sequenced on and off, with a defined duty-cycle. In this example, these durations are defined to give roughly a 50% duty-cycle, which allows a corresponding reduction in the preamble-hunt power consumption while still being able to receive frames. It is suggested that the simple TX example, from 6.3.1 above, is used as a source of frames to test this.

Note: SNIFF mode reduces RX sensitivity depending on the on and off period configurations. Please see the DW3000 User Manual [2] for more details

6.3.13 Example 02f: RX with XTAL trimming

This is an example of a receiver that measures the clock offset of a remote transmitter and then uses the XTAL trimming function to modify the local clock to achieve a target clock offset. Note: To keep a system stable it is recommended to only adjust trimming at one end of a link.

6.3.14 Example 02g: simple RX with STS

This example is very similar to Example 2a, 6.3.10 above, except that it is using STS configuration.

6.3.15 Example 02h: simple RX with PDOA

This example is very similar to Example 2a, 6.3.10 above, except that it is using PDOA configuration.

6.3.16 Example 02i: simple RX AES

This example application waits indefinitely for an incoming frame (is expects a 802.15.8 sample frame from companion 6.3.9 example). When a frame is received, it starts to examine the frame residing in the RX buffer. It checks sizes validity and then extract the header from this buffer. According to this header and header size, it builds the nonce and get the payload size, before attempting to decrypt the payload.

6.3.17 Example 03a: TX then wait for a response

This example application is a combination of examples 1a and 2a. This example sends a frame then waits for a response (with receive timeout enabled). If a response is received, it is stored in a local buffer for examination and then flow proceeds to the transmission of the next frame. If a response is not received, the timeout will trigger, and the application will proceed to the next transmission.

6.3.18 Example 03b: RX then send a response

This example application is the complement of example 3a. It waits indefinitely for a frame. When a frame is received, it is stored in a local buffer. If the received frame is the one transmitted by the example 3a application, then a response is sent. In any case, when the received frame is processed this simple example application re-enables the receiver to start waiting again for another frame.

6.3.19 Example 03d: TX then wait for a response using interrupts

This is a variation of example 3a where interrupts and call-backs are used to process received frames, reception errors and timeouts and transmission confirmation instead of polling with an infinite loop.

6.3.20 Example 04a: continuous wave mode

This example application activates continuous wave mode for 2 minutes with a predefined configuration. On a correctly configured spectrum analyser (use configuration values on the picture below), the output should look like this:

**Figure 8: Continuous wave output**

6.3.21 Example 04b: continuous frame mode

This example application activates continuous frame mode for 2 minutes with a predefined configuration. On a correctly configured spectrum analyser (use configuration values on the picture below), the output should look like this:

Figure 9: Continuous frame output

6.3.22 Example 05a: double-sided two-way ranging (DS TWR) initiator

This is a simple code example that acts as the initiator in a DS TWR distance measurement exchange. This application sends a “poll” frame (recording the TX time-stamp of the poll), and then waits for a “response” message expected from the “DS TWR responder” example code (companion to this application – see section [6.3.23 below](#)). When the response is received its RX time-stamp is recorded and we send a “final” message to complete the exchange. The final message contains all the time-stamps recorded by this application, including the calculated/predicted TX time-stamp for the final message itself. The companion “DS TWR responder” example application works out the time-of-flight over-the-air and, thus, the estimated distance between the two devices.

Included in this directory in the examples source code is another version of the code described above that uses STS Mode 1 frames instead of STS Mode 0 frames. This means that the frames that are sent and received use an STS to compute distance measurements. For more details on STS, please read the IEEE 802.15.4z documentation.

6.3.23 Example 05b: double-sided two-way ranging (DS TWR) responder

This is a simple code example that acts as the responder in a DS TWR distance measurement exchange. This application waits for a “poll” message (recording the RX time-stamp of the poll) expected from the “DS TWR initiator” example code (companion to this application), and then sends a “response” message recording its TX time-stamp, after which it waits for a “final” message from the initiator to complete the exchange. The final message contains the remote initiator’s time-stamps of poll TX, response RX and final TX. With this data and the local time-stamps, (of poll RX, response TX and final RX), this example application works out a value for the time-of-flight over-the-air and, thus, the estimated distance between the two devices, which it writes to the LCD.

Included in this directory in the examples source code is another version of the code described above that uses STS Mode 1 frames instead of STS Mode 0 frames. This means that the frames that

are sent and received use an STS to compute distance measurements. For more details on STS, please read the IEEE 802.15.4z documentation.

6.3.24 Example 05c: double-sided two-way ranging with STS (DS TWR STS) initiator

This is an extension based on example 5a (see section [6.3.22 above](#)), except that the STS mode is also configured. Thus when good frame reception occurs, STS quality is checked and validated before the STS timestamps are used to work out the range. The companion to this example is DS TWR STS responder is described in section [6.3.25 below](#).

6.3.25 Example 05d: double-sided two-way ranging with STS (DS TWR STS) responder

This is a companion example to DW TWR STS initiator (see section [6.3.24 above](#)) and is based on DW TWR responder example (see section [6.3.23 above](#)) with the addition of STS.

6.3.26 Example 06a: single-sided two-way ranging (SS TWR) initiator

This is a simple code example that acts as the initiator in a SS TWR distance measurement exchange. This application sends a “poll” frame (recording the TX time-stamp of the poll), after which it waits for a “response” message from the “SS TWR responder” example code (companion to this application) to complete the exchange. The response message contains the remote responder’s time-stamps of poll RX, and response TX. With this data and the local time-stamps, (of poll TX and response RX), this example application works out a value for the time-of-flight over-the-air and, thus, the estimated distance between the two devices, which it writes to the LCD.

Heretofore, we would have recommended use of double-sided TWR (as per examples 5a and 5b) instead of this single-sided two-way ranging because the SS-TWR time-of-flight estimation typically suffers poor accuracy due to the clock offset between the two nodes participating in the TWR exchange. However since driver version 4.0.6 we are now making use of the carrier integrator diagnostic from the IC (accessible via the new [dwt_readcarrierintegrator\(\)](#) API function) to measure the clock offset and improve the accuracy SS-TWR range estimate calculation.

Included in this directory in the examples source code is another version of the code described above that uses STS Mode 1 frames instead of STS Mode 0 frames. This means that the frames that are sent and received use an STS to compute distance measurements. For more details on STS, please read the IEEE 802.15.4z documentation.

Also included in this directory in the examples source code is another version of the code described above that uses STS Mode 3 packets instead of STS Mode 0 frames. The “poll” and “response” messages contain no payload and are only used for computing timestamps using STS. An STS Mode 0 frame is sent from the receiver to the initiator which contains the required timestamp data to compute distance values in this particular transaction of signals. For more details on STS, please read the IEEE 802.15.4z documentation.

6.3.27 Example 06b: single-sided two-way ranging (SS TWR) responder

This is a simple code example that acts as the responder in a SS TWR distance measurement exchange. This application waits for a “poll” message (recording the RX time-stamp of the poll) expected from the “SS TWR initiator” example code (companion to this application), and then sends a “response” message to complete the exchange. The response message contains all the time-stamps recorded by this application, including the calculated/predicted TX time-stamp for the response message itself. The companion “SS TWR initiator” example application works out the time-of-flight over-the-air and, thus, the estimated distance between the two devices.

Included in this directory in the examples source code is another version of the code described above that uses STS Mode 1 frames instead of STS Mode 0 frames. This means that the frames that are sent and received use an STS to compute distance measurements. For more details on STS, please read the IEEE 802.15.4z documentation.

Also included in this directory in the examples source code is another version of the code described above that uses STS Mode 3 packets instead of STS Mode 0 frames. The “poll” and “response” messages contain no payload and are only used for computing timestamps using STS. An STS Mode 0 frame is sent from the receiver to the initiator which contains the required timestamp data to compute distance values in this particular transaction of signals. For more details on STS, please read the IEEE 802.15.4z documentation.

6.3.28 Example 06e: single-sided two-way ranging (SS TWR) initiator with AES

This is a simple code example that acts as the initiator in a SS TWR distance measurement exchange. This application sends a “poll” frame (recording the TX time-stamp of the poll), after which it waits for a “response” message from the “SS TWR responder” example code (companion to this application) to complete the exchange. The response message contains the remote responder’s time-stamps of poll RX, and response TX. With this data and the local time-stamps, (of poll TX and response RX), this example application works out a value for the time-of-flight over-the-air and, thus, the estimated distance between the two devices, which it writes to the LCD.

This example uses a simple MAC frame – 802.15.4. It has a source address, destination address and key index for encryption.

The Initiator sends encrypted tx_poll_msg message to the responder.

The responder will replay with its own encrypted rx_resp_msg, but this time with a different key index and it will switch between the source address and destination address.

Both Initiator and responder will check if the data is for them, meaning data is encrypted and with the right source and destination address. The responder puts its time signature results in the first 8 bytes of the rx_resp_msg.

Heretofore, we would have recommended use of double-sided TWR (as per examples 5a and 5b) instead of this single-sided two-way ranging because the SS-TWR time-of-flight estimation typically suffers poor accuracy due to the clock offset between the two nodes participating in the TWR exchange. However since driver version 4.0.6 we are now making use of the carrier integrator

diagnostic from the IC (accessible via the new [`dwt_readcarrierintegrator\(\)`](#) API function) to measure the clock offset and improve the accuracy SS-TWR range estimate calculation.

6.3.29 Example 06f: single-sided two-way ranging responder (SS TWR) with AES

This is a simple code example that acts as the responder in a SS TWR distance measurement exchange. This application waits for a “poll” message (recording the RX time-stamp of the poll) expected from the “SS TWR initiator” example code (companion to this application), and then sends a “response” message to complete the exchange. The response message contains all the time-stamps recorded by this application, including the calculated/predicted TX time-stamp for the response message itself. The companion “SS TWR initiator” example application works out the time-of-flight over-the-air and, thus, the estimated distance between the two devices.

This example uses a simple MAC frame – 802.15.4. It has a source address, destination address and key index for encryption.

The Responder replies to the Initiator with encrypted rx_resp_msg message.

The responder replay will be with a different key index and it will switch between the source address and destination address.

Both Initiator and responder will check if the data is for them, meaning data is encrypted and with the right source and destination address. The responder puts its time signature results in the first 8 bytes of the rx_resp_msg.

6.3.30 Example 07a: Auto ACK TX

This example, with its companion example 8b below, demonstrates the operation of the IC’s auto-ACK function. The code here is based on example 3a, except that in this case the transmitted frame has the AR (acknowledgement request) bit set in the frame control field of the MAC header, (following the MAC frame definitions of IEEE 802.15.4 [3]), and the turn-around to await response is immediate, reflecting the ACK response timing of the IC.

6.3.31 Example 07b: Auto ACK RX

This complement to example 8a. Here the Auto ACK feature of IC is activated so that frames sent by companion example 8a are automatically acknowledged.

6.3.32 Example 11a: Use of SPI CRC

This example shows the use of SPI CRC feature.

6.3.33 Example 13a: Use of DW3000 GPIO lines

This example demonstrates how to enable the GPIO lines as inputs and output

6.3.34 Example 14: OTP Write

This example illustrates how a user can write and verify data to addresses in the OTP memory.

6.3.35 Example 15: LE (Low-Energy) pend

This example illustrates how a user can utilise the “LE Pend” (Low-Energy Pending) features of the DW3000 device. A TX device will transmit a frame to an RX device. The RX device will acknowledge this frame (with an ACK frame) if the following conditions are met:

- The TX frame is an IEEE 802.14.5 MAC command frame.
The frame is received from a device with an address that is pre-programmed into the DW3000 LE_PEND01 or LE_PEND23 registers.

10 ABOUT DECAWAVE

Decawave is a pioneering fabless semiconductor company whose flagship product, the DW3000, is a complete, single chip CMOS Ultra-Wideband IC based on the IEEE 802.15.4 standard UWB PHY. This device is the first in a family of parts.

The resulting silicon has a wide range of standards-based applications for both Real Time Location Systems (RTLS) and Ultra Low Power Wireless Transceivers in areas as diverse as manufacturing, healthcare, lighting, security, transport, and inventory and supply-chain management.

For further information on this or any other Decawave product contact a sales representative as follows: -

Decawave Ltd,
Adelaide Chambers,
Peter Street,
Dublin D08 T6YA,
Ireland.
